## Arb Documentation

*Release 2.11.1*

Fredrik Johansson

Oct 19, 2017

# CONTENTS

|          |   |           |
|----------|---|-----------|
| <b>1</b> | <b>Introduction</b>   | <b>1</b>  |
| <b>2</b> | <b>General information</b>  | <b>3</b>  |
| 2.1      | Feature overview . . . . .  | 3         |
| 2.2      | Setup . . . . .   | 4         |
| 2.2.1    | Package managers . . . . .  | 4         |
| 2.2.2    | Download . . . . .  | 4         |
| 2.2.3    | Dependencies . . . . .  | 4         |
| 2.2.4    | Standalone installation . . . . .   | 5         |
| 2.2.5    | Running tests . . . . .   | 5         |
| 2.2.6    | Installation as part of FLINT (deprecated) . . . . .                                | 5         |
| 2.2.7    | Building with MSVC . . . . .  | 6         |
| 2.2.8    | Running code . . . . .  | 6         |
| 2.3      | Using ball arithmetic . . . . .   | 7         |
| 2.3.1    | Ball semantics . . . . .  | 7         |
| 2.3.2    | Binary and decimal . . . . .  | 7         |
| 2.3.3    | Quality of enclosures . . . . .   | 8         |
| 2.3.4    | Predicates . . . . .  | 9         |
| 2.3.5    | A worked example: the sine function . . . . .                                       | 10        |
| 2.3.6    | More on precision and accuracy . . . . .  | 12        |
| 2.3.7    | Polynomial time guarantee . . . . .   | 13        |
| 2.4      | Technical conventions and potential issues . . . . .                                | 13        |
| 2.4.1    | Integer types . . . . .   | 13        |
| 2.4.2    | Integer overflow . . . . .  | 14        |
| 2.4.3    | Aliasing . . . . .  | 15        |
| 2.4.4    | Thread safety and caches . . . . .  | 16        |
| 2.4.5    | Use of hardware floating-point arithmetic . . . . .                                 | 16        |
| 2.4.6    | Interface changes . . . . .   | 16        |
| 2.4.7    | General note on correctness . . . . .   | 17        |
| 2.5      | Example programs . . . . .  | 17        |
| 2.5.1    | pi.c . . . . .  | 17        |
| 2.5.2    | hilbert_matrix.c . . . . .  | 17        |
| 2.5.3    | keiper_li.c . . . . .   | 18        |
| 2.5.4    | logistic.c . . . . .  | 19        |
| 2.5.5    | real_roots.c . . . . .  | 19        |
| 2.5.6    | poly_roots.c . . . . .  | 22        |
| 2.5.7    | complex_plot.c . . . . .  | 24        |
| 2.5.8    | lvalue.c . . . . .  | 25        |
| <b>3</b> | <b>Floating-point numbers</b>   | <b>27</b> |
| 3.1      | <b>mag.h</b> – fixed-precision unsigned floating-point numbers for bounds . . . . . | 27        |
| 3.1.1    | Types, macros and constants . . . . .   | 27        |
| 3.1.2    | Memory management . . . . .   | 27        |
| 3.1.3    | Special values . . . . .  | 28        |

|        |   |    |
|--------|---|----|
| 3.1.4  | Comparisons   | 28 |
| 3.1.5  | Input and output  | 28 |
| 3.1.6  | Random generation   | 28 |
| 3.1.7  | Conversions   | 29 |
| 3.1.8  | Arithmetic  | 29 |
| 3.1.9  | Fast, unsafe arithmetic                                   | 30 |
| 3.1.10 | Powers and logarithms                                     | 30 |
| 3.1.11 | Special functions   | 31 |
| 3.2    | <b>arf.h</b> – arbitrary-precision floating-point numbers | 32 |
| 3.2.1  | Types, macros and constants                               | 32 |
| 3.2.2  | Memory management   | 33 |
| 3.2.3  | Special values  | 33 |
| 3.2.4  | Assignment, rounding and conversions                      | 34 |
| 3.2.5  | Comparisons and bounds                                    | 36 |
| 3.2.6  | Magnitude functions                                       | 36 |
| 3.2.7  | Shallow assignment  | 37 |
| 3.2.8  | Random number generation                                  | 37 |
| 3.2.9  | Input and output  | 37 |
| 3.2.10 | Addition and multiplication                               | 38 |
| 3.2.11 | Summation   | 39 |
| 3.2.12 | Division  | 39 |
| 3.2.13 | Square roots  | 39 |
| 3.2.14 | Complex arithmetic  | 40 |
| 3.2.15 | Low-level methods   | 40 |
| 4      | <b>Real and complex numbers</b>                           | 41 |
| 4.1    | <b>arb.h</b> – real numbers                               | 41 |
| 4.1.1  | Types, macros and constants                               | 42 |
| 4.1.2  | Memory management   | 42 |
| 4.1.3  | Assignment and rounding                                   | 43 |
| 4.1.4  | Assignment of special values                              | 43 |
| 4.1.5  | Input and output  | 44 |
| 4.1.6  | Random number generation                                  | 44 |
| 4.1.7  | Radius and interval operations                            | 45 |
| 4.1.8  | Comparisons   | 47 |
| 4.1.9  | Arithmetic  | 48 |
| 4.1.10 | Powers and roots  | 50 |
| 4.1.11 | Exponentials and logarithms                               | 51 |
| 4.1.12 | Trigonometric functions                                   | 52 |
| 4.1.13 | Inverse trigonometric functions                           | 53 |
| 4.1.14 | Hyperbolic functions                                      | 53 |
| 4.1.15 | Inverse hyperbolic functions                              | 53 |
| 4.1.16 | Constants   | 53 |
| 4.1.17 | Lambert W function  | 54 |
| 4.1.18 | Gamma function and factorials                             | 54 |
| 4.1.19 | Zeta function   | 55 |
| 4.1.20 | Bernoulli numbers and polynomials                         | 56 |
| 4.1.21 | Polylogarithms  | 57 |
| 4.1.22 | Other special functions                                   | 57 |
| 4.1.23 | Internals for computing elementary functions              | 58 |
| 4.1.24 | Vector functions  | 59 |
| 4.2    | <b>acb.h</b> – complex numbers                            | 60 |
| 4.2.1  | Types, macros and constants                               | 61 |
| 4.2.2  | Memory management   | 61 |
| 4.2.3  | Basic manipulation  | 61 |
| 4.2.4  | Input and output  | 62 |
| 4.2.5  | Random number generation                                  | 63 |
| 4.2.6  | Precision and comparisons                                 | 63 |

|          |  |           |
|----------|--|-----------|
| 4.2.7    | Complex parts . . . . .  | 64        |
| 4.2.8    | Arithmetic . . . . .   | 65        |
| 4.2.9    | Mathematical constants . . . . .                                   | 66        |
| 4.2.10   | Powers and roots . . . . .   | 66        |
| 4.2.11   | Exponentials and logarithms . . . . .                              | 67        |
| 4.2.12   | Trigonometric functions . . . . .                                  | 67        |
| 4.2.13   | Inverse trigonometric functions . . . . .                          | 68        |
| 4.2.14   | Hyperbolic functions . . . . .                                     | 68        |
| 4.2.15   | Inverse hyperbolic functions . . . . .                             | 68        |
| 4.2.16   | Lambert W function . . . . .                                       | 68        |
| 4.2.17   | Rising factorials . . . . .  | 69        |
| 4.2.18   | Gamma function . . . . .   | 70        |
| 4.2.19   | Zeta function . . . . .  | 71        |
| 4.2.20   | Polylogarithms . . . . .   | 71        |
| 4.2.21   | Arithmetic-geometric mean . . . . .                                | 71        |
| 4.2.22   | Other special functions . . . . .                                  | 71        |
| 4.2.23   | Vector functions . . . . .   | 72        |
| <b>5</b> | <b>Polynomials and power series</b>                                | <b>75</b> |
| 5.1      | <b>arb_poly.h</b> – polynomials over the real numbers . . . . .    | 75        |
| 5.1.1    | Types, macros and constants . . . . .                              | 75        |
| 5.1.2    | Memory management . . . . .  | 75        |
| 5.1.3    | Basic manipulation . . . . .                                       | 76        |
| 5.1.4    | Conversions . . . . .  | 77        |
| 5.1.5    | Input and output . . . . .   | 77        |
| 5.1.6    | Random generation . . . . .  | 77        |
| 5.1.7    | Comparisons . . . . .  | 77        |
| 5.1.8    | Bounds . . . . .   | 77        |
| 5.1.9    | Arithmetic . . . . .   | 78        |
| 5.1.10   | Composition . . . . .  | 80        |
| 5.1.11   | Evaluation . . . . .   | 81        |
| 5.1.12   | Product trees . . . . .  | 82        |
| 5.1.13   | Multipoint evaluation . . . . .                                    | 83        |
| 5.1.14   | Interpolation . . . . .  | 83        |
| 5.1.15   | Differentiation . . . . .  | 83        |
| 5.1.16   | Transforms . . . . .   | 84        |
| 5.1.17   | Powers and elementary functions . . . . .                          | 84        |
| 5.1.18   | Lambert W function . . . . .                                       | 88        |
| 5.1.19   | Gamma function and factorials . . . . .                            | 88        |
| 5.1.20   | Zeta function . . . . .  | 88        |
| 5.1.21   | Root-finding . . . . .   | 89        |
| 5.1.22   | Other special polynomials . . . . .                                | 90        |
| 5.2      | <b>acb_poly.h</b> – polynomials over the complex numbers . . . . . | 90        |
| 5.2.1    | Types, macros and constants . . . . .                              | 90        |
| 5.2.2    | Memory management . . . . .  | 91        |
| 5.2.3    | Basic properties and manipulation . . . . .                        | 91        |
| 5.2.4    | Input and output . . . . .   | 92        |
| 5.2.5    | Random generation . . . . .  | 92        |
| 5.2.6    | Comparisons . . . . .  | 92        |
| 5.2.7    | Conversions . . . . .  | 93        |
| 5.2.8    | Bounds . . . . .   | 93        |
| 5.2.9    | Arithmetic . . . . .   | 93        |
| 5.2.10   | Composition . . . . .  | 95        |
| 5.2.11   | Evaluation . . . . .   | 96        |
| 5.2.12   | Product trees . . . . .  | 97        |
| 5.2.13   | Multipoint evaluation . . . . .                                    | 97        |
| 5.2.14   | Interpolation . . . . .  | 98        |
| 5.2.15   | Differentiation . . . . .  | 98        |

|          |  |            |
|----------|--|------------|
| 5.2.16   | Transforms   | 98         |
| 5.2.17   | Elementary functions   | 99         |
| 5.2.18   | Lambert W function   | 102        |
| 5.2.19   | Gamma function   | 102        |
| 5.2.20   | Power sums   | 103        |
| 5.2.21   | Zeta function  | 103        |
| 5.2.22   | Other special functions  | 104        |
| 5.2.23   | Root-finding   | 105        |
| 5.3      | <b>arb_fmpz_poly.h</b> – extra methods for integer polynomials       | 106        |
| 5.3.1    | Evaluation   | 106        |
| 5.3.2    | Utility methods  | 107        |
| 5.3.3    | Polynomial roots   | 107        |
| 5.3.4    | Special polynomials  | 108        |
| <b>6</b> | <b>Matrices</b>  | <b>109</b> |
| 6.1      | <b>arb_mat.h</b> – matrices over the real numbers                    | 109        |
| 6.1.1    | Types, macros and constants  | 109        |
| 6.1.2    | Memory management  | 109        |
| 6.1.3    | Conversions  | 110        |
| 6.1.4    | Random generation  | 110        |
| 6.1.5    | Input and output   | 110        |
| 6.1.6    | Comparisons  | 110        |
| 6.1.7    | Special matrices   | 110        |
| 6.1.8    | Transpose  | 111        |
| 6.1.9    | Norms  | 111        |
| 6.1.10   | Arithmetic   | 111        |
| 6.1.11   | Scalar arithmetic  | 111        |
| 6.1.12   | Gaussian elimination and solving                                     | 112        |
| 6.1.13   | Cholesky decomposition and solving                                   | 112        |
| 6.1.14   | Characteristic polynomial  | 114        |
| 6.1.15   | Special functions  | 114        |
| 6.1.16   | Sparsity structure   | 114        |
| 6.2      | <b>acb_mat.h</b> – matrices over the complex numbers                 | 115        |
| 6.2.1    | Types, macros and constants  | 115        |
| 6.2.2    | Memory management  | 115        |
| 6.2.3    | Conversions  | 115        |
| 6.2.4    | Random generation  | 115        |
| 6.2.5    | Input and output   | 116        |
| 6.2.6    | Comparisons  | 116        |
| 6.2.7    | Special matrices   | 116        |
| 6.2.8    | Transpose  | 116        |
| 6.2.9    | Norms  | 116        |
| 6.2.10   | Arithmetic   | 117        |
| 6.2.11   | Scalar arithmetic  | 117        |
| 6.2.12   | Gaussian elimination and solving                                     | 118        |
| 6.2.13   | Characteristic polynomial  | 118        |
| 6.2.14   | Special functions  | 118        |
| <b>7</b> | <b>Higher mathematical functions</b>                                 | <b>121</b> |
| 7.1      | <b>acb_hypgeom.h</b> – hypergeometric functions of complex variables | 121        |
| 7.1.1    | Convergent series  | 121        |
| 7.1.2    | Asymptotic series  | 123        |
| 7.1.3    | Generalized hypergeometric function                                  | 123        |
| 7.1.4    | Confluent hypergeometric functions                                   | 123        |

## INTRODUCTION

Welcome to Arb’s documentation! Arb is a C library for arbitrary-precision interval arithmetic, using a midpoint-radius representation (“ball arithmetic”). It supports real and complex numbers, polynomials, power series, matrices, and evaluation of many transcendental functions. All operations are done with automatic, rigorous error bounds. The code is thread-safe, portable, and extensively tested.

Arb is free software distributed under the GNU Lesser General Public License (LGPL), version 2.1 or later (see *License*).

The git repository is <https://github.com/fredrik-johansson/arb/>

Arb is developed by Fredrik Johansson ([fredrik.johansson@gmail.com](mailto:fredrik.johansson@gmail.com)), with help from many contributors (see *Credits and references*). Questions and discussion about Arb are welcome on the [flint-devel](#) mailing list. There is also an [issue tracker](#) for bug reports and feature requests. Development progress is sometimes covered on [Fredrik’s blog](#).

This documentation is available in HTML format at <http://arblib.org> and in PDF format at <http://arblib.org/arb.pdf>. The version of the documentation you are currently reading was updated Oct 19, 2017 and describes Arb 2.11.1. Documentation for *specific release versions* is also available in PDF format.

## GENERAL INFORMATION

### 2.1 Feature overview

Arb builds upon [FLINT](#), which deals with efficient computation over exact domains such as the rational numbers and finite fields. Arb extends FLINT to cover computations with real and complex numbers. The problem when computing with real and complex numbers is that approximations (typically floating-point numbers) must be used, potentially leading to incorrect results.

Ball arithmetic, also known as mid-rad interval arithmetic, is an extension of floating-point arithmetic in which an error bound is attached to each variable. This allows computing rigorously with real and complex numbers.

With plain floating-point arithmetic, the user must do an error analysis to guarantee that results are correct. Manual error analysis is time-consuming and bug-prone. Ball arithmetic effectively makes error analysis automatic.

In traditional (inf-sup) interval arithmetic, both endpoints of an interval  $[a, b]$  are full-precision numbers, which makes interval arithmetic twice as expensive as floating-point arithmetic. In ball arithmetic, only the midpoint  $m$  of an interval  $[m \pm r]$  is a full-precision number, and a few bits suffice for the radius  $r$ . At high precision, ball arithmetic is therefore not more expensive than plain floating-point arithmetic.

Joris van der Hoeven's paper [\[Hoe2009\]](#) is a good introduction to the subject.

Other implementations of ball arithmetic include [iRRAM](#) and [Mathemagix](#). Arb differs from earlier implementations in technical aspects of the implementation, which makes certain computations more efficient. It also provides a more comprehensive low-level interface, giving the user full access to the internals. Finally, it implements a wider range of transcendental functions, covering a large portion of the special functions in standard reference works such as [\[NIST2012\]](#).

Arb is designed for computer algebra and computational number theory, but may be useful in any area demanding reliable or precise numerical computing. Arb scales seamlessly from tens of digits up to billions of digits. Efficiency is achieved by low level optimizations and use of asymptotically fast algorithms.

Arb contains:

- A module (*arf*) for correctly rounded arbitrary-precision floating-point arithmetic. Arb's floating-point numbers have a few special features, such as arbitrary-size exponents (useful for combinatorics and asymptotics) and dynamic allocation (facilitating implementation of hybrid integer/floating-point and mixed-precision algorithms).
- A module (*mag*) for representing magnitudes (error bounds) more efficiently than with an arbitrary-precision floating-point type.
- A module (*arb*) for real ball arithmetic, where a ball is implemented as an *arf* midpoint and a *mag* radius.
- A module (*acb*) for complex numbers in rectangular form, represented as pairs of real balls.

- Modules (*arb\_poly*, *acb\_poly*) for polynomials or power series over the real and complex numbers, implemented using balls as coefficients, with asymptotically fast polynomial multiplication and many other operations.
- Modules (*arb\_mat*, *acb\_mat*) for matrices over the real and complex numbers, implemented using balls as coefficients. At the moment, only rudimentary linear algebra operations are provided.
- Functions for high-precision evaluation of various mathematical constants and special functions, implemented using ball arithmetic with rigorous error bounds.

Arb 1.x used a different set of numerical base types (*fmpr*, *fmprb* and *fmpcb*). These types had a slightly simpler internal representation, but generally had worse performance. All methods for the Arb 1.x types have now been ported to faster equivalents for the Arb 2.x types. The last version to include both the Arb 1.x and Arb 2.x types and methods was Arb 2.2. As of Arb 2.9, only a small set of *fmpr* methods are left for fallback and testing purposes.

Arb uses **GMP** / **MPFR** and **FLINT** for the underlying integer arithmetic and various utility functions. Arb also uses **MPFR** for testing purposes and internally to evaluate some functions.

## 2.2 Setup

### 2.2.1 Package managers

The easiest way to install Arb including all dependencies is via ready-made packages available for various distributions. Note that some packages may not be up to date.

- Debian / Ubuntu / Linux Mint
  - <https://packages.debian.org/source/sid/flint-arb>
- Fedora
  - <https://admin.fedoraproject.org/pkgdb/package/rpms/arb/>
- Arch Linux
  - [https://www.archlinux.org/packages/community/x86\\_64/arb/](https://www.archlinux.org/packages/community/x86_64/arb/)
  - <https://www.archlinux.org/packages/community/i686/arb/>
- Guix
  - <https://www.gnu.org/software/guix/packages/>

### 2.2.2 Download

Tarballs of released versions can be downloaded from <https://github.com/fredrik-johansson/arb/releases>

Alternatively, you can simply install Arb from a git checkout of <https://github.com/fredrik-johansson/arb/>. The master branch is generally safe to use (the test suite should pass at all times), and recommended for keeping up with the latest improvements and bug fixes.

### 2.2.3 Dependencies

Arb has the following dependencies:

- Either **MPFR** (<http://www.mpir.org>) 2.6.0 or later, or **GMP** (<http://www.gmp.org>) 5.1.0 or later. If MPFR is used instead of GMP, it must be compiled with the `--enable-gmpcompat` option.
- **MPFR** (<http://www.mpir.org>) 3.0.0 or later.

- FLINT (<http://www.flintlib.org>) version 2.5 or later. You may also use a git checkout of <https://github.com/fredrik-johansson/flint2>

## 2.2.4 Standalone installation

To compile, test and install Arb from source as a standalone library, first install FLINT. Then go to the Arb source directory and run:

```
./configure <options>
make
make check      (optional)
make install
```

If GMP/MPFR, MPFR or FLINT is installed in some other location than the default path `/usr/local`, pass `--with-gmp=...`, `--with-mpfr=...` or `--with-flint=...` with the correct path to configure (type `./configure --help` to show more options).

After the installation, you may have to run `ldconfig` to make sure that the system's dynamic linker finds the library.

On a multicore system, `make` can be run with the `-j` flag to build in parallel. For example, use `make -j4` on a quad-core machine.

## 2.2.5 Running tests

After running `make`, it is recommended to also run `make check` to verify that all unit tests pass.

By default, the unit tests run a large number of iterations to improve the chances of detecting subtle problems. The whole test suite might take around 20 minutes on a single core (`make -jN check` if you have more cores to spare). If you are in a hurry, you can adjust the number of test iterations via the `ARB_TEST_MULTIPLIER` environment variable. For example, the following will only run 10% of the default iterations:

```
export ARB_TEST_MULTIPLIER=0.1
make check
```

It is also possible to run the unit tests for a single module, for instance:

```
make check MOD=arb_poly
```

## 2.2.6 Installation as part of FLINT (deprecated)

WARNING: this feature is being deprecated. Please install Arb as a separate library, as detailed above.

With some versions of FLINT, Arb can be compiled as a FLINT extension package.

Simply put the Arb source directory somewhere, say `/path/to/arb`. Then go to the FLINT source directory and build FLINT using:

```
./configure --extensions=/path/to/arb <other options>
make
make check      (optional)
make install
```

This is convenient, as Arb does not need to be configured or linked separately. Arb becomes part of the compiled FLINT library, and the Arb header files will be installed along with the other FLINT header files.

## 2.2.7 Building with MSVC

To compile arb with MSVC, compile MPIR, MPFR, pthreads-win32 and FLINT using MSVC. Install CMake  $\geq 2.8.12$  and make sure it is in the path. Then go to the Arb source directory and run:

```
mkdir build
cd build
cmake ..                                # configure
cmake --build . --config Release        # build
cmake --build . --config Release --target install # install
```

To build a Debug build, create a new build directory and pass `-DCMAKE_BUILD_TYPE=Debug` to `cmake`. To create a dll library, pass `-DBUILD_SHARED_LIBS=yes` to `cmake`. Note that creating a dll library requires CMake  $\geq 3.5.0$

If the dependencies are not found, pass `-DCMAKE_PREFIX_PATH=/path/to/deps` to `cmake` to find the dependencies.

To build tests add, pass `-DBUILD_TESTS=yes` to `cmake` and run `ctest` to run the tests.

## 2.2.8 Running code

Here is an example program to get started using Arb:

```
#include "arb.h"

int main()
{
    arb_t x;
    arb_init(x);
    arb_const_pi(x, 50 * 3.33);
    arb_printn(x, 50, 0); flint_printf("\n");
    flint_printf("Computed with arb-%s\n", arb_version);
    arb_clear(x);
}
```

Compile it with:

```
gcc test.c -larb
```

Depending on the environment, you may also have to pass the flags `-lflint`, `-lmpfr`, `-lgmp` to the compiler.

If the Arb/FLINT header and library files are not in a standard location (`/usr/local` on most systems), you may also have to provide flags such as:

```
-I/path/to/arb -I/path/to/flint -L/path/to/flint -L/path/to/arb
```

Finally, to run the program, make sure that the linker can find the FLINT (and Arb) libraries. If they are installed in a nonstandard location, you can for example add this path to the `LD_LIBRARY_PATH` environment variable.

The output of the example program should be something like the following:

```
[3.1415926535897932384626433832795028841971693993751 +/- 6.28e-50]
Computed with arb-2.4.0
```

## 2.3 Using ball arithmetic

This section gives an introduction to working with real numbers in Arb (see [arb.h – real numbers](#) for the API and technical documentation). The general principles carry over to complex numbers, polynomials and matrices.

### 2.3.1 Ball semantics

Let  $f : A \rightarrow B$  be a function. A ball implementation of  $f$  is a function  $F$  that maps sets  $X \subseteq A$  to sets  $F(X) \subseteq B$  subject to the following rule:

For all  $x \in X$ , we have  $f(x) \in F(X)$ .

In other words,  $F(X)$  is an *enclosure* for the set  $\{f(x) : x \in X\}$ . This rule is sometimes called the *inclusion principle*.

Throughout the documentation (except where otherwise noted), we will simply write  $f(x)$  instead of  $F(X)$  when describing ball implementations of pointwise-defined mathematical functions, understanding that the input is a set of point values and that the output is an enclosure.

General subsets of  $\mathbb{R}$  are not possible to represent on a computer. Instead, we work with subsets of the form  $[m \pm r] = [m - r, m + r]$  where the midpoint  $m$  and radius  $r$  are binary floating-point numbers, i.e. numbers of the form  $u2^v$  with  $u, v \in \mathbb{Z}$  (to make this scheme complete, we also need to adjoin the special floating-point values  $-\infty$ ,  $+\infty$  and NaN).

Given a ball  $[m \pm r]$  with  $m \in \mathbb{R}$  (not necessarily a floating-point number), we can always round  $m$  to a nearby floating-point number that has at most  $prec$  bits in the component  $u$ , and add an upper bound for the rounding error to  $r$ . In Arb, ball functions that take a *prec* argument as input (e.g. [arb\\_add\(\)](#)) always round their output to *prec* bits. Some functions are always exact (e.g. [arb\\_neg\(\)](#)), and thus do not take a *prec* argument.

The programming interface resembles that of GMP. Each [arb\\_t](#) variable must be initialized with [arb\\_init\(\)](#) before use (this also sets its value to zero), and deallocated with [arb\\_clear\(\)](#) after use. Variables have pass-by-reference semantics. In the list of arguments to a function, output variables come first, followed by input variables, and finally the precision:

```
#include "arb.h"

int main()
{
    arb_t x, y;
    arb_init(x); arb_init(y);
    arb_set_ui(x, 3);          /* x = 3 */
    arb_const_pi(y, 128);      /* y = pi, to 128 bits */
    arb_sub(y, y, x, 53);      /* y = y - x, to 53 bits */
    arb_clear(x); arb_clear(y);
}
```

### 2.3.2 Binary and decimal

While the internal representation uses binary floating-point numbers, it is usually preferable to print numbers in decimal. The binary-to-decimal conversion generally requires rounding. Three different methods are available for printing a number to standard output:

- [arb\\_print\(\)](#) shows the exact internal representation of a ball, with binary exponents.
- [arb\\_printd\(\)](#) shows an inexact view of the internal representation, approximated by decimal floating-point numbers.
- [arb\\_printn\(\)](#) shows a *decimal ball* that is guaranteed to be an enclosure of the binary floating-point ball. By default, it only prints digits in the midpoint that are certain to be correct, up to an

error of at most one unit in the last place. Converting from binary to decimal is generally inexact, and the output of this method takes this rounding into account when printing the radius.

This snippet computes a 53-bit enclosure of  $\pi$  and prints it in three ways:

```
arb_const_pi(x, 53);
arb_print(x); printf("\n");
arb_printd(x, 20); printf("\n");
arb_printn(x, 20, 0); printf("\n");
```

The output is:

```
(884279719003555 * 2^-48) +/- (536870913 * 2^-80)
3.141592653589793116 +/- 4.4409e-16
[3.141592653589793 +/- 5.61e-16]
```

The `arb_get_str()` and `arb_set_str()` methods are useful for converting rigorously between decimal strings and binary balls (`arb_get_str()` produces the same string as `arb_printn()`, and `arb_set_str()` can parse such strings back).

A potential mistake is to create a ball from a `double` constant such as 2.3, when this actually represents 2.29999999999999982236431605997495353221893310546875. To produce a ball containing the rational number 23/10, one of the following can be used:

```
arb_set_str(x, "2.3", prec)

arb_set_ui(x, 23);
arb_div_ui(x, x, 10, prec)

fmpq_set_si(q, 23, 10); /* q is a FLINT fmpq_t */
arb_set_fmpq(x, q, prec);
```

### 2.3.3 Quality of enclosures

The main problem when working with ball arithmetic (or interval arithmetic) is *overestimation*. In general, the enclosure of a value or set of values as computed with ball arithmetic will be larger than the smallest possible enclosure.

Overestimation results naturally from rounding errors and cancellations in the individual steps of a calculation. As a general principle, formula rewriting techniques that make floating-point code more numerically stable also make ball arithmetic code more numerically stable, in the sense of producing tighter enclosures.

As a result of the *dependency problem*, ball or interval arithmetic can produce error bounds that are much larger than the actual numerical errors resulting from doing floating-point arithmetic. Consider the expression  $(x + 1) - x$  as an example. When evaluated in floating-point arithmetic,  $x$  may have a large initial error. However, that error will cancel itself out in the subtraction, so that the result equals 1 (except perhaps for a small rounding error left from the operation  $x + 1$ ). In ball arithmetic, dependent errors add up instead of cancelling out. If  $x = [3 \pm 0.1]$ , the result will be  $[1 \pm 0.2]$ , where the error bound has doubled. In unfavorable circumstances, error bounds can grow exponentially with the number of steps.

If all inputs to a calculation are “point values”, i.e. exact numbers and known mathematical constants that can be approximated arbitrarily closely (such as  $\pi$ ), then an error of order  $2^n$  can typically be overcome by working with  $n$  extra bits of precision, increasing the computation time by an amount that is polynomial in  $n$ . In certain situations, however, overestimation leads to exponential slowdown or even failure of an algorithm to converge. For example, root-finding algorithms that refine the result iteratively may fail to converge in ball arithmetic, even if they do converge in plain floating-point arithmetic.

Therefore, ball arithmetic is not a silver bullet: there will always be situations where some amount of numerical or mathematical analysis is required. Some experimentation may be required to find whether (and how) it can be used effectively for a given problem.

### 2.3.4 Predicates

A ball implementation of a predicate  $f : \mathbb{R} \rightarrow \{\text{True}, \text{False}\}$  would need to be able to return a third logical value indicating that the result could be either True or False. In most cases, predicates in Arb are implemented as functions that return the *int* value 1 to indicate that the result certainly is True, and the *int* value 0 to indicate that the result could be either True or False. To test whether a predicate certainly is False, the user must test whether the negated predicate certainly is True.

For example, the following code would *not* be correct in general:

```
if (arb_is_positive(x))
{
    ... /* do things assuming that x > 0 */
}
else
{
    ... /* do things assuming that x <= 0 */
}
```

Instead, the following can be used:

```
if (arb_is_positive(x))
{
    ... /* do things assuming that x > 0 */
}
else if (arb_is_nonpositive(x))
{
    ... /* do things assuming that x <= 0 */
}
else
{
    ... /* do things assuming that the sign of x is unknown */
}
```

Likewise, we will write  $x \leq y$  in mathematical notation with the meaning that  $x \leq y$  holds for all  $x \in X, y \in Y$  where  $X$  and  $Y$  are balls.

Note that some predicates such as `arb_overlaps()` and `arb_contains()` actually are predicates on balls viewed as sets, and not ball implementations of pointwise predicates.

Some predicates are also complementary. For example `arb_contains_zero()` tests whether the input ball contains the point zero. Negated, it is equivalent to `arb_is_nonzero()`, and complementary to `arb_is_zero()` as a pointwise predicate:

```
if (arb_is_zero(x))
{
    ... /* do things assuming that x = 0 */
}
#ifdef 1
else if (arb_is_nonzero(x))
#else
else if (!arb_contains_zero(x)) /* equivalent */
#endif
{
    ... /* do things assuming that x != 0 */
}
else
{
    ... /* do things assuming that the sign of x is unknown */
}
```

### 2.3.5 A worked example: the sine function

We implement the function  $\sin(x)$  naively using the Taylor series  $\sum_{k=0}^{\infty} (-1)^k x^{2k+1} / (2k+1)!$  and `arb_t` arithmetic. Since there are infinitely many terms, we need to split the series in two parts: a finite sum that can be evaluated directly, and a tail that has to be bounded.

We stop as soon as we reach a term  $t$  bounded by  $|t| \leq 2^{-prec} < 1$ . The terms are alternating and must have decreasing magnitude from that point, so the tail of the series is bounded by  $|t|$ . We add this magnitude to the radius of the output. Since ball arithmetic automatically bounds the numerical errors resulting from all arithmetic operations, the output `res` is a ball guaranteed to contain  $\sin(x)$ .

```
#include "arb.h"

void arb_sin_naive(arb_t res, const arb_t x, slong prec)
{
    arb_t s, t, u, tol;
    slong k;
    arb_init(s); arb_init(t); arb_init(u); arb_init(tol);

    arb_one(tol);
    arb_mul_2exp_si(tol, tol, -prec); /* tol = 2^-prec */

    for (k = 0; ; k++)
    {
        arb_pow_ui(t, x, 2 * k + 1, prec);
        arb_fac_ui(u, 2 * k + 1, prec);
        arb_div(t, t, u, prec); /* t = x^(2k+1) / (2k+1)! */

        arb_abs(u, t);
        if (arb_le(u, tol)) /* if |t| <= 2^-prec */
        {
            arb_add_error(s, u); /* add |t| to the radius and stop */
            break;
        }

        if (k % 2 == 0)
            arb_add(s, s, t, prec);
        else
            arb_sub(s, s, t, prec);
    }

    arb_set(res, s);
    arb_clear(s); arb_clear(t); arb_clear(u); arb_clear(tol);
}
```

This algorithm is naive, because the Taylor series is slow to converge and suffers from catastrophic cancellation when  $|x|$  is large (we could also improve the efficiency of the code slightly by computing the terms using recurrence relations instead of computing  $x^k$  and  $k!$  from scratch each iteration).

As a test, we compute  $\sin(2016.1)$ . The largest term in the Taylor series for  $\sin(x)$  reaches a magnitude of about  $x^x/x!$ , or about  $10^{873}$  in this case. Therefore, we need over 873 digits (about 3000 bits) of precision to overcome the catastrophic cancellation and determine the result with sufficient accuracy to tell whether it is positive or negative.

```
int main()
{
    arb_t x, y;
    slong prec;
    arb_init(x); arb_init(y);

    for (prec = 64; ; prec *= 2)
    {
```

```

    arb_set_str(x, "2016.1", prec);
    arb_sin_naive(y, x, prec);
    printf("Using %5ld bits, sin(x) = ", prec);
    arb_printn(y, 10, 0); printf("\n");
    if (!arb_contains_zero(y)) /* stopping condition */
        break;
}

arb_clear(x); arb_clear(y);
}

```

The program produces the following output:

```

Using    64 bits, sin(x) = [+/- 2.67e+859]
Using   128 bits, sin(x) = [+/- 1.30e+840]
Using   256 bits, sin(x) = [+/- 3.60e+801]
Using   512 bits, sin(x) = [+/- 3.01e+724]
Using  1024 bits, sin(x) = [+/- 2.18e+570]
Using  2048 bits, sin(x) = [+/- 1.22e+262]
Using  4096 bits, sin(x) = [-0.7190842207 +/- 1.20e-11]

```

As an exercise, the reader may improve the naive algorithm by making it subtract a well-chosen multiple of  $2\pi$  from  $x$  before invoking the Taylor series (hint: use `arb_const_pi()`, `arb_div()` and `arf_get_fmpz()`). If done correctly, 64 bits of precision should be more than enough to compute  $\sin(2016.1)$ , and with minor adjustments to the code, the user should be able to compute  $\sin(\exp(2016.1))$  quite easily as well.

This example illustrates how ball arithmetic can be used to perform nontrivial calculations. To evaluate an infinite series, the user needs to know how to bound the tail of the series, but everything else is automatic. When evaluating a finite formula that can be expressed completely using built-in functions, all error bounding is automatic from the point of view of the user. In particular, the `arb_sin()` method should be used to compute the sine of a real number; it uses a much more efficient algorithm than the naive code above.

This example also illustrates the “guess-and-verify” paradigm: instead of determining *a priori* the floating-point precision necessary to get a correct result, we *guess* some initial precision, use ball arithmetic to *verify* that the result is accurate enough, and restart with higher precision (or signal failure) if it is not.

If we think of rounding errors as essentially random processes, then a floating-point computation is analogous to a *Monte Carlo algorithm*. Using ball arithmetic to get a verified result effectively turns it into the analog of a *Las Vegas algorithm*, which is a randomized algorithm that always gives a correct result if it terminates, but may fail to terminate (alternatively, instead of actually looping forever, it might signal failure after a certain number of iterations).

The loop will fail to terminate if we attempt to determine the sign of  $\sin(\pi)$ :

```

Using    64 bits, sin(x) = [+/- 3.96e-18]
Using   128 bits, sin(x) = [+/- 2.17e-37]
Using   256 bits, sin(x) = [+/- 6.10e-76]
Using   512 bits, sin(x) = [+/- 5.13e-153]
Using  1024 bits, sin(x) = [+/- 4.01e-307]
Using  2048 bits, sin(x) = [+/- 2.13e-615]
Using  4096 bits, sin(x) = [+/- 6.85e-1232]
Using  8192 bits, sin(x) = [+/- 6.46e-2465]
Using 16384 bits, sin(x) = [+/- 5.09e-4931]
Using 32768 bits, sin(x) = [+/- 5.41e-9863]
...

```

The sign of a nonzero real number can be decided by computing it to sufficiently high accuracy, but the sign of an expression that is exactly equal to zero cannot be decided by a numerical computation unless the entire computation happens to be exact (in this example, we could use the `arb_sin_pi()` function

which computes  $\sin(\pi x)$  in one step, with the input  $x = 1$ ).

It is up to the user to implement a stopping criterion appropriate for the circumstances of a given application. For example, breaking when it is clear that  $|\sin(x)| < 10^{-10000}$  would allow the program to terminate and convey some meaningful information about the input  $x = \pi$ , though this would not constitute a mathematical proof that  $\sin(\pi) = 0$ .

## 2.3.6 More on precision and accuracy

The relation between the working precision and the accuracy of the output is not always easy predict. The following remarks might help to choose *prec* optimally.

For a ball  $[m \pm r]$  it is convenient to define the following notions:

- Absolute error:  $e_{abs} = |r|$
- Relative error:  $e_{rel} = |r| / \max(0, |m| - |r|)$  (or  $e_{rel} = 0$  if  $r = m = 0$ )
- Absolute accuracy:  $a_{abs} = 1/e_{abs}$
- Relative accuracy:  $a_{rel} = 1/e_{rel}$

Expressed in bits, one takes the corresponding  $\log_2$  values.

Of course, if  $x$  is the exact value being approximated, then the “absolute error” so defined is an upper bound for the actual absolute error  $|x - m|$  and “absolute accuracy” a lower bound for  $1/|x - m|$ , etc.

The *prec* argument in Arb should be thought of as controlling the working precision. Generically, when evaluating a fixed expression (that is, when the sequence of operations does not depend on the precision), the absolute or relative error will be bounded by

$$2^{O(1)-prec}$$

where the  $O(1)$  term depends on the expression and implementation details of the ball functions used to evaluate it. Accordingly, for an accuracy of  $p$  bits, we need to use a working precision  $O(1) + p$ . If the expression is numerically well-behaved, then the  $O(1)$  term will be small, which leads to the heuristic of “adding a few guard bits” (for most basic calculations, 10 or 20 guard bits is enough). If the  $O(1)$  term is unknown, then increasing the number of guard bits in exponential steps until the result is accurate enough is generally a good heuristic.

Sometimes, a partially accurate result can be used to estimate the  $O(1)$  term. For example, if the goal is to achieve 100 bits of accuracy and a precision of 120 bits yields 80 bits of accuracy, then it is plausible that a precision of just over 140 bits yields 100 bits of accuracy.

Built-in functions in Arb can roughly be characterized as belonging to one of two extremes (though there is actually a spectrum):

- Simple operations, including basic arithmetic operations and many elementary functions. In most cases, for an input  $x = [m \pm r]$ ,  $f(x)$  is evaluated by computing  $f(m)$  and then separately bounding the *propagated error*  $|f(m) - f(m + \varepsilon)|$ ,  $|\varepsilon| \leq r$ . The working precision is automatically increased internally so that  $f(m)$  is computed to *prec* bits of relative accuracy with an error of at most a few units in the last place (perhaps with rare exceptions). The propagated error can generally be bounded quite tightly as well (see [General formulas and bounds](#)). As a result, the enclosure will be close to the best possible at the given precision, and the user can estimate the precision to use accordingly.
- Complex operations, such as certain higher transcendental functions (for example, the Riemann zeta function). The function is evaluated by performing a sequence of simpler operations, each using ball arithmetic with a working precision of roughly *prec* bits. The sequence of operations might depend on *prec*; for example, an infinite series might be truncated so that the remainder is smaller than  $2^{-prec}$ . The final result can be far from tight, and it is not guaranteed that the error converges to zero as  $prec \rightarrow \infty$ , though in practice, it should do so in most cases.

In short, the *inclusion principle* is the fundamental contract in Arb. Enclosures computed by built-in functions may or may not be tight enough to be useful, but the hope is that they will be sufficient for most purposes. Tightening the error bounds for more complex operations is a long term optimization goal, which in many cases will require a fair amount of research. A tradeoff also has to be made for efficiency: tighter error bounds allow the user to work with a lower precision, but they may also be much more expensive to compute.

### 2.3.7 Polynomial time guarantee

Arb provides a soft guarantee that the time used to evaluate a ball function will depend polynomially on *prec* and the bit size of the input, uniformly regardless of the numerical value of the input.

The idea behind this soft guarantee is to allow Arb to be used as a black box to evaluate expressions numerically without potentially slowing down, hanging indefinitely or crashing because of “bad” input such as nested exponentials. By controlling the precision, the user can cancel a computation before it uses up an unreasonable amount of resources, without having to rely on other timeout or exception mechanisms. A result that is feasible but very expensive to compute can still be forced by setting the precision high enough.

As motivation, consider evaluating  $\sin(x)$  or  $\exp(x)$  with the exact floating-point number  $x = 2^{2^n}$  as input. The time and space required to compute an accurate floating-point approximation of  $\sin(x)$  or  $\exp(x)$  increases as  $2^n$ , in the first case because of the need to subtract an accurate multiple of  $2\pi$  and in the second case due to the size of the output exponent and the internal subtraction of an accurate multiple of  $\log(2)$ . This is despite the fact that the size of  $x$  as an object in memory only increases linearly with  $n$ . Already  $n = 33$  would require at least 1 GB of memory, and  $n = 100$  would be physically impossible to process. For functions that are computed by direct use of power series expansions, e.g.  $f(x) = \sum_{k=0}^{\infty} c_k x^k$ , without having fast argument-reduction techniques like those for elementary functions, the time would be exponential in  $n$  already when  $x = 2^n$ .

Therefore, Arb caps internal work parameters (the internal working precision, the number terms of an infinite series to add, etc.) by polynomial, usually linear, functions of *prec*. When the limit is exceeded, the output is set to a crude bound. For example, if  $x$  is too large, `arb_sin()` will simply return  $[\pm 1]$ , and `arb_exp()` will simply return  $[\pm \infty]$  if  $x$  is positive or  $[\pm 2^{-m}]$  if  $x$  is negative.

This is not just a failsafe, but occasionally a useful optimization. It is not entirely uncommon to have formulas where one term is modest and another term decreases exponentially, such as:

$$\log(x) + \sin(x) \exp(-x).$$

For example, the reflection formula of the digamma function has a similar structure. When  $x$  is large, the right term would be expensive to compute to high relative accuracy. Doing so is unnecessary, however, since a crude bound of  $[\pm 1] \cdot [\pm 2^{-m}]$  is enough to evaluate the expression as a whole accurately.

The polynomial time guarantee is “soft” in that there are a few exceptions. For example, the complexity of computing the Riemann zeta function  $\zeta(\sigma + it)$  increases linearly with the imaginary height  $|t|$  in the current implementation, and all known algorithms have a complexity of  $|t|^\alpha$  where the best known value for  $\alpha$  is about 0.3. Input with large  $|t|$  is most likely to be given deliberately by users with the explicit intent of evaluating the zeta function itself, so the evaluation is not cut off automatically.

## 2.4 Technical conventions and potential issues

### 2.4.1 Integer types

Arb generally uses the *int* type for boolean values and status flags.

The *char*, *short* and *int* types are assumed to be two’s complement types with exactly 8, 16 and 32 bits. This is not technically guaranteed by the C standard, but there are no mainstream platforms where this assumption does not hold, and new ones are unlikely to appear in the near future (ignoring certain low-power DSPs and the like, which are out of scope for this software).

Since the C types *long* and *unsigned long* do not have a standardized size in practice, FLINT defines *slong* and *ulong* types which are guaranteed to be 32 bits on a 32-bit system and 64 bits on a 64-bit system. They are also guaranteed to have the same size as GMP's *mp\_limb\_t*. GMP builds with a different limb size configuration are not supported at all. For convenience, the macro *FLINT\_BITS* specifies the word length (32 or 64) of the system.

#### **slong**

The *slong* type is used for precisions, bit counts, loop indices, array sizes, and the like, even when those values are known to be nonnegative. It is also used for small integer-valued coefficients. In method names, an *slong* parameter is denoted by *si*, for example *arb\_add\_si()*.

The constants *WORD\_MIN* and *WORD\_MAX* give the range of this type. This type can be printed with *flint\_printf* using the format string *%wd*.

#### **ulong**

The *ulong* type is used for integer-valued coefficients that are known to be unsigned, and for values that require the full 32-bit or 64-bit range. In method names, a *ulong* parameter is denoted by *ui*, for example *arb\_add\_ui()*.

The constant *UWORD\_MAX* gives the range of this type. This type can be printed with *flint\_printf* using the format string *%wu*.

The following GMP-defined types are used in methods that manipulate the internal representation of numbers (using limb arrays).

#### **mp\_limb\_t**

A single limb.

#### **mp\_ptr**

Pointer to a writable array of limbs.

#### **mp\_srcptr**

Pointer to a read-only array of limbs.

#### **mp\_size\_t**

A limb count (always nonnegative).

#### **mp\_bitcnt\_t**

A bit offset within an array of limbs (always nonnegative).

Arb uses the following FLINT types for exact (integral and rational) arbitrary-size values. For details, refer to the FLINT documentation.

#### **fmpz\_t**

The FLINT multi-precision integer type uses an inline representation for small integers, specifically when the absolute value is at most  $2^{62} - 1$  (on 64-bit machines) or  $2^{30} - 1$  (on 32-bit machines). It switches automatically to a GMP integer for larger values. The *fmpz\_t* type is functionally identical to the GMP *mpz\_t* type, but faster for small values.

#### **fmpq\_t**

FLINT multi-precision rational number.

#### **fmpz\_poly\_t**

#### **fmpq\_poly\_t**

#### **fmpz\_mat\_t**

#### **fmpq\_mat\_t**

FLINT polynomials and matrices with integer and rational coefficients.

## **2.4.2 Integer overflow**

When machine-size integers are used for precisions, sizes of integers in bits, lengths of polynomials, and similar quantities that relate to sizes in memory, very few internal checks are performed to verify that such quantities do not overflow.

Precisions and lengths exceeding a small fraction of `LONG_MAX`, say  $2^{24} \approx 10^7$  on 32-bit systems, should be regarded as resulting in undefined behavior. On 64-bit systems this should generally not be an issue, since most calculations will exhaust the available memory (or the user's patience waiting for the computation to complete) long before running into integer overflows. However, the user needs to be wary of unintentionally passing input parameters of order `LONG_MAX` or negative parameters where positive parameters are expected, for example due to a runaway loop that repeatedly increases the precision.

Currently, no hard upper limit on the precision is defined, but  $2^{24} \approx 10^7$  bits on 32-bit system and  $2^{36} \approx 10^{11}$  bits on a 64-bit system can be considered safe for most purposes. The relatively low limit on 64-bit systems is due to the fact that GMP integers are used internally in some algorithms, and GMP integers are limited to  $2^{37}$  bits. The minimum allowed precision is 2 bits.

This caveat does not apply to exponents of floating-point numbers, which are represented as arbitrary-precision integers, nor to integers used as numerical scalars (e.g. `arb_mul_si()`). However, it still applies to conversions and operations where the result is requested exactly and sizes become an issue. For example, trying to convert the floating-point number  $2^{2^{100}}$  to an integer could result in anything from a silent wrong value to thrashing followed by a crash, and it is the user's responsibility not to attempt such a thing.

### 2.4.3 Aliasing

As a rule, Arb allows aliasing of operands. For example, in the function call `arb_add(z, x, y, prec)`, which performs  $z \leftarrow x + y$ , any two (or all three) of the variables  $x$ ,  $y$  and  $z$  are allowed to be the same. Exceptions to this rule are documented explicitly.

The general rule that input and output variables can be aliased with each other only applies to variables *of the same type* (ignoring `const` qualifiers on input variables – a special case is that `arb_srcptr` is considered the `const` version of `arb_ptr`). This is a natural extension of the so-called *strict aliasing rule* in C.

For example, in `arb_poly_evaluate()` which evaluates  $y = f(x)$  for a polynomial  $f$ , the output variable  $y$  is not allowed to be a pointer to one of the coefficients of  $f$  (but aliasing between  $x$  and  $y$  or between  $x$  and the coefficients of  $f$  is allowed). This also applies to `_arb_poly_evaluate()`: for the purposes of aliasing, `arb_srcptr` (the type of the coefficient array within  $f$ ) and `arb_t` (the type of  $x$ ) are *not* considered to be the same type, and therefore must not be aliased with each other, even though an `arb_ptr/arb_srcptr` variable pointing to a length 1 array would otherwise be interchangeable with an `arb_t/const arb_t`.

Moreover, in functions that allow aliasing between an input array and an output array, the arrays must either be identical or completely disjoint, never partially overlapping.

There are natural exceptions to these aliasing restrictions, which may be used internally without being documented explicitly. However, third party code should avoid relying on such exceptions.

An important caveat applies to **aliasing of input variables**. Identical pointers are understood to give permission for **algebraic simplification**. This assumption is made to improve performance. For example, the call `arb_mul(z, x, x, prec)` sets  $z$  to a ball enclosing the set

$$\{t^2 : t \in x\}$$

and not the (generally larger) set

$$\{tu : t \in x, u \in x\}.$$

If the user knows that two values  $x$  and  $y$  both lie in the interval  $[-1, 1]$  and wants to compute an enclosure for  $f(x, y)$ , then it would be a mistake to create an `arb_t` variable  $x$  enclosing  $[-1, 1]$  and reusing the same variable for  $y$ , calling  $f(x, x)$ . Instead, the user has to create a distinct variable  $y$  also enclosing  $[-1, 1]$ .

Algebraic simplification is not guaranteed to occur. For example, `arb_add(z, x, x, prec)` and `arb_sub(z, x, x, prec)` currently do not implement this optimization. It is better to use `arb_mul_2exp_si(z, x, 1)` and `arb_zero(z)`, respectively.

### 2.4.4 Thread safety and caches

Arb should be fully threadsafe, provided that both MPFR and FLINT have been built in threadsafe mode. Use `flint_set_num_threads()` to set the number of threads that Arb is allowed to use internally for single computations (this is currently only exploited by a handful of operations). Please note that thread safety is only tested minimally, and extra caution when developing multithreaded code is therefore recommended.

Arb may cache some data (such as the value of  $\pi$  and Bernoulli numbers) to speed up various computations. In threadsafe mode, caches use thread-local storage. There is currently no way to save memory and avoid recomputation by having several threads share the same cache. Caches can be freed by calling the `flint_cleanup()` function. To avoid memory leaks, the user should call `flint_cleanup()` when exiting a thread. It is also recommended to call `flint_cleanup()` when exiting the main program (this should result in a clean output when running `Valgrind`, and can help catching memory issues).

There does not seem to be an obvious way to make sure that `flint_cleanup()` is called when exiting a thread using OpenMP. A possible solution to this problem is to use OpenMP sections, or to use C++ and create a thread-local object whose destructor invokes `flint_cleanup()`.

### 2.4.5 Use of hardware floating-point arithmetic

Arb uses hardware floating-point arithmetic (the `double` type in C) in two different ways.

Firstly, `double` arithmetic as well as transcendental `libm` functions (such as `exp`, `log`) are used to select parameters heuristically in various algorithms. Such heuristic use of approximate arithmetic does not affect correctness: when any error bounds depend on the parameters, the error bounds are evaluated separately using rigorous methods. At worst, flaws in the floating-point arithmetic on a particular machine could cause an algorithm to become inefficient due to inefficient parameters being selected.

Secondly, `double` arithmetic is used internally for some rigorous error bound calculations. To guarantee correctness, we make the following assumptions. With the stated exceptions, these should hold on all commonly used platforms.

- A `double` uses the standard IEEE 754 format (with a 53-bit significand, 11-bit exponent, encoding of infinities and NaNs, etc.)
- We assume that the compiler does not perform “unsafe” floating-point optimizations, such as reordering of operations. Unsafe optimizations are disabled by default in most modern C compilers, including GCC and Clang. The exception appears to be the Intel C++ compiler, which does some unsafe optimizations by default. These must be disabled by the user.
- We do not assume that floating-point operations are correctly rounded (a counterexample is the x87 FPU), or that rounding is done in any particular direction (the rounding mode may have been changed by the user). We assume that any floating-point operation is done with at most 1.1 ulp error.
- We do not assume that underflow or overflow behaves in a particular way (we only use doubles that fit in the regular exponent range, or explicit infinities).
- We do not use transcendental `libm` functions, since these can have errors of several ulps, and there is unfortunately no way to get guaranteed bounds. However, we do use functions such as `ldexp` and `sqrt`, which we assume to be correctly implemented.

### 2.4.6 Interface changes

Most of the core API should be stable at this point, and significant compatibility-breaking changes will be specified in the release notes.

In general, Arb does not distinguish between “private” and “public” parts of the API. The implementation is meant to be transparent by design. All methods are intended to be fully documented and tested (exceptions to this are mainly due to lack of time on part of the author). The user should use common

sense to determine whether a function is concerned with implementation details, making it likely to change as the implementation changes in the future. The interface of `arb_add()` is probably not going to change in the next version, but `_arb_get_mpn_fixed_mod_pi4()` just might.

## 2.4.7 General note on correctness

Except where otherwise specified, Arb is designed to produce provably correct error bounds. The code has been written carefully, and the library is extensively tested. However, like any complex mathematical software, Arb is virtually certain to contain bugs, so the usual precautions are advised:

- Do sanity checks. For example, check that the result satisfies an expected mathematical relation, or compute the same result in two different ways, with different settings, and with different levels of precision. Arb's unit tests already do such checks, but they are not guaranteed to catch every possible bug, and they provide no protection against the user accidentally using the interface incorrectly.
- Compare results with other mathematical software.
- Read the source code to verify that it really does what it is supposed to do.

All bug reports are highly appreciated.

## 2.5 Example programs

The *examples* directory (<https://github.com/fredrik-johansson/arb/tree/master/examples>) contains several complete C programs, which are documented below. Running:

```
make examples
```

will compile the programs and place the binaries in `build/examples`.

### 2.5.1 pi.c

This program computes  $\pi$  to an accuracy of roughly  $n$  decimal digits by calling the `arb_const_pi()` function with a working precision of roughly  $n \log_2(10)$  bits.

Sample output, computing  $\pi$  to one million digits:

```
> build/examples/pi 1000000
computing pi with a precision of 3321933 bits... cpu/wall(s): 0.58 0.586
virt/peak/res/peak(MB): 28.24 36.84 8.86 15.56
[3.14159265358979323846{...999959 digits...}42209010610577945815 +/- 3e-1000000]
```

The program prints an interval guaranteed to contain  $\pi$ , and where all displayed digits are correct up to an error of plus or minus one unit in the last place (see `arb_printn()`). By default, only the first and last few digits are printed. Pass 0 as a second argument to print all digits (or pass  $m$  to print  $m + 1$  leading and  $m$  trailing digits, as above with the default  $m = 20$ ).

### 2.5.2 hilbert\_matrix.c

Given an input integer  $n$ , this program accurately computes the determinant of the  $n$  by  $n$  Hilbert matrix. Hilbert matrices are notoriously ill-conditioned: although the entries are close to unit magnitude, the determinant  $h_n$  decreases superexponentially (nearly as  $1/4^{n^2}$ ) as a function of  $n$ . This program automatically doubles the working precision until the ball computed for  $h_n$  by `arb_mat_det()` does not contain zero.

Sample output:

```
> build/examples/hilbert_matrix 200
prec=20: 0 +/- 5.5777e-330
prec=40: 0 +/- 2.5785e-542
prec=80: 0 +/- 8.1169e-926
prec=160: 0 +/- 2.8538e-1924
prec=320: 0 +/- 6.3868e-4129
prec=640: 0 +/- 1.7529e-8826
prec=1280: 0 +/- 1.8545e-17758
prec=2560: 2.955454297e-23924 +/- 6.4586e-24044
success!
cpu/wall(s): 9.06 9.095
virt/peak/res/peak(MB): 55.52 55.52 35.50 35.50
```

### 2.5.3 keiper\_li.c

Given an input integer  $n$ , this program rigorously computes numerical values of the Keiper-Li coefficients  $\lambda_0, \dots, \lambda_n$ . The Keiper-Li coefficients have the property that  $\lambda_n > 0$  for all  $n > 0$  if and only if the Riemann hypothesis is true. This program was used for the record computations described in [Joh2013] (the paper describes the algorithm in some more detail).

The program takes the following parameters:

```
keiper_li n [-prec prec] [-threads num_threads] [-out out_file]
```

The program prints the first and last few coefficients. It can optionally write all the computed data to a file. The working precision defaults to a value that should give all the coefficients to a few digits of accuracy, but can optionally be set higher (or lower). On a multicore system, using several threads results in faster execution.

Sample output:

```
> build/examples/keiper_li 1000 -threads 2
zeta: cpu/wall(s): 0.4 0.244
virt/peak/res/peak(MB): 167.98 294.69 5.09 7.43
log: cpu/wall(s): 0.03 0.038
gamma: cpu/wall(s): 0.02 0.016
binomial transform: cpu/wall(s): 0.01 0.018

virt/peak/res/peak(MB): 170.18 294.69 7.51 7.51
```

### 2.5.4 logistic.c

This program computes the  $n$ -th iterate of the logistic map defined by  $x_{n+1} = rx_n(1 - x_n)$  where  $r$  and  $x_0$  are given. It takes the following parameters:

```
logistic n [x_0] [r] [digits]
```

The inputs  $x_0$ ,  $r$  and *digits* default to 0.5, 3.75 and 10 respectively. The computation is automatically restarted with doubled precision until the result is accurate to *digits* decimal digits.

Sample output:

```
> build/examples/logistic 10
Trying prec=64 bits...success!
cpu/wall(s): 0 0.001
x_10 = [0.6453672908 +/- 3.10e-11]

### 2.5.5 real\_roots.c

This program isolates the roots of a function on the interval  $(a, b)$  (where  $a$  and  $b$  are input as double-precision literals) using the routines in the *arb\_calc* module. The program takes the following arguments:

```
real_roots function a b [-refine d] [-verbose] [-maxdepth n] [-maxeval n] [-maxfound n] [-prec ↵
↵n]
```

The following functions (specified by an integer code) are implemented:

- 0 -  $Z(x)$  (Riemann-Siegel Z-function)
- 1 -  $\sin(x)$

- 2 -  $\sin(x^2)$
- 3 -  $\sin(1/x)$
- 4 -  $\text{Ai}(x)$  (Airy function)
- 5 -  $\text{Ai}'(x)$  (Airy function)
- 6 -  $\text{Bi}(x)$  (Airy function)
- 7 -  $\text{Bi}'(x)$  (Airy function)

The following options are available:

- **-refine d**: If provided, after isolating the roots, attempt to refine the roots to  $d$  digits of accuracy using a few bisection steps followed by Newton's method with adaptive precision, and then print them.
- **-verbose**: Print more information.
- **-maxdepth n**: Stop searching after  $n$  recursive subdivisions.
- **-maxeval n**: Stop searching after approximately  $n$  function evaluations (the actual number evaluations will be a small multiple of this).
- **-maxfound n**: Stop searching after having found  $n$  isolated roots.
- **-prec n**: Working precision to use for the root isolation.

With *function* 0, the program isolates roots of the Riemann zeta function on the critical line, and guarantees that no roots are missed (there are more efficient ways to do this, but it is a nice example):

```
> build/examples/real_roots 0 0.0 50.0 -verbose
interval: [0, 50]
maxdepth = 30, maxeval = 100000, maxfound = 100000, low_prec = 30
found isolated root in: [14.111328125, 14.16015625]

```

Find roots of  $\sin(x^2)$  on  $(0, 100)$ . The algorithm cannot isolate the root at  $x = 0$  (it is at the endpoint of the interval, and in any case a root of multiplicity higher than one). The failure is reported:

```
> build/examples/real_roots 2 0 100
interval: [0, 100]
maxdepth = 30, maxeval = 100000, maxfound = 100000, low_prec = 30
-----

virt/peak/res/peak(MB): 26.32 26.37 2.01 2.01
```

Looking for roots of  $\sin(1/x)$  on  $(0, 1)$ , the algorithm finds many roots, but will never find all of them since there are infinitely many:

```
> build/examples/real_roots 3 0.0 1.0
interval: [0, 1]
maxdepth = 30, maxeval = 100000, maxfound = 100000, low_prec = 30
-----
Found roots: 10198
```

```
Subintervals possibly containing undetected roots: 24695
Function evaluations: 202587
cpu/wall(s): 0.171 0.171
virt/peak/res/peak(MB): 28.39 30.38 4.05 4.05
```

Remark: the program always computes rigorous containing intervals for the roots, but the accuracy after refinement could be less than  $d$  digits.

## 2.5.6 poly\_roots.c

This program finds the complex roots of an integer polynomial by calling `arb_fmpz_poly_complex_roots()`, which in turn calls `acb_poly_find_roots()` with increasing precision until the roots certainly have been isolated. The program takes the following arguments:

```
poly_roots [-refine d] [-print d] <poly>
```

Isolates all the complex roots of a polynomial with integer coefficients.

If `-refine d` is passed, the roots are refined to a relative tolerance better than  $10^{-(d)}$ . By default, the roots are only computed to sufficient accuracy to isolate them. The refinement is not currently done efficiently.

If `-print d` is passed, the computed roots are printed to  $d$  decimals. By default, the roots are not printed.

The polynomial can be specified by passing the following as `<poly>`:

```
a <n>          Easy polynomial  $1 + 2x + \dots + (n+1)x^n$ 
t <n>          Chebyshev polynomial  $T_n$ 
u <n>          Chebyshev polynomial  $U_n$ 
p <n>          Legendre polynomial  $P_n$ 
c <n>          Cyclotomic polynomial  $\Phi_n$ 
s <n>          Swinnerton-Dyer polynomial  $S_n$ 
b <n>          Bernoulli polynomial  $B_n$ 
w <n>          Wilkinson polynomial  $W_n$ 
e <n>          Taylor series of  $\exp(x)$  truncated to degree  $n$ 
m <n> <m>       The Mignotte-like polynomial  $x^n + (100x+1)^m$ ,  $n > m$ 
coeffs <c0 c1 ... cn>       $c_0 + c_1 x + \dots + c_n x^n$ 
```

Concatenate to multiply polynomials, e.g.: `p 5 t 6 coeffs 1 2 3`  
for  $P_5(x) \cdot T_6(x) \cdot (1+2x+3x^2)$

This finds the roots of the Wilkinson polynomial with roots at the positive integers 1, 2, ..., 100:

```
> build/examples/poly_roots -print 15 w 100

### 2.5.7 complex\_plot.c

This program plots one of the predefined functions over a complex interval  $[x_a, x_b] + [y_a, y_b]i$  using domain coloring, at a resolution of  $xn$  times  $yn$  pixels.

The program takes the parameters:

```
complex_plot [-range xa xb ya yb] [-size xn yn] <func>
```

Defaults parameters are  $[-10, 10] + [-10, 10]i$  and  $xn = yn = 512$ .

The output is written to `arbplot.ppm`. If you have ImageMagick, run `convert arbplot.ppm arbplot.png` to get a PNG.

Function codes `<func>` are:

- `gamma` - Gamma function
- `digamma` - Digamma function
- `lgamma` - Logarithmic gamma function
- `zeta` - Riemann zeta function
- `erf` - Error function
- `ai` - Airy function Ai
- `bi` - Airy function Bi
- `besselj` - Bessel function  $J_0$
- `bessely` - Bessel function  $Y_0$
- `besseli` - Bessel function  $I_0$
- `besselk` - Bessel function  $K_0$
- `modj` - Modular j-function
- `modeta` - Dedekind eta function
- `barnesg` - Barnes G-function
- `agm` - Arithmetic geometric mean

The function is just sampled at point values; no attempt is made to resolve small features by adaptive subsampling.

For example, the following plots the Riemann zeta function around a portion of the critical strip with imaginary part between 100 and 140:

```
> build/examples/complex_plot zeta -range -10 10 100 140 -size 256 512
```

## 2.5.8 lvalue.c

This program evaluates Dirichlet L-functions. It takes the following input:

```
> build/examples/lvalue
lvalue [-character q n] [-re a] [-im b] [-prec p] [-z] [-deflate] [-len l]

Print value of Dirichlet L-function at  $s = a+bi$ .
Default  $a = 0.5$ ,  $b = 0$ ,  $p = 53$ ,  $(q, n) = (1, 0)$  (Riemann zeta)
[-z]      - compute  $Z(s)$  instead of  $L(s)$ 
[-deflate] - remove singular term at  $s = 1$ 
[-len l]  - compute  $l$  terms in Taylor series at  $s$ 
```

Evaluating the Riemann zeta function and the Dirichlet beta function at  $s = 2$ :

```
> build/examples/lvalue -re 2 -prec 128
L(s) = [1.64493406684822643647241516664602518922 +/- 4.37e-39]
cpu/wall(s): 0.001 0.001
virt/peak/res/peak(MB): 26.86 26.88 2.05 2.05

> build/examples/lvalue -character 4 3 -re 2 -prec 128
L(s) = [0.91596559417721901505460351493238411077 +/- 7.86e-39]
cpu/wall(s): 0.002 0.003
virt/peak/res/peak(MB): 26.86 26.88 2.31 2.31
```

Evaluating the L-function for character number 101 modulo 1009 at  $s = 1/2$  and  $s = 1$ :

```
> build/examples/lvalue -character 1009 101
L(s) = [-0.459256562383872 +/- 5.24e-16] + [1.346937111206009 +/- 3.03e-16]*I
cpu/wall(s): 0.012 0.012
virt/peak/res/peak(MB): 26.86 26.88 2.30 2.30

> build/examples/lvalue -character 1009 101 -re 1
L(s) = [0.657952586112728 +/- 6.02e-16] + [1.004145273214022 +/- 3.10e-16]*I
cpu/wall(s): 0.017 0.018
virt/peak/res/peak(MB): 26.86 26.88 2.30 2.30
```

Computing the first few coefficients in the Laurent series of the Riemann zeta function at  $s = 1$ :

```
> build/examples/lvalue -re 1 -deflate -len 8
L(s) = [0.577215664901532861 +/- 5.29e-19]
L'(s) = [0.072815845483676725 +/- 2.68e-19]
[x^2] L(s+x) = [-0.004845181596436159 +/- 3.87e-19]
[x^3] L(s+x) = [-0.000342305736717224 +/- 4.20e-19]
[x^4] L(s+x) = [9.6890419394471e-5 +/- 2.40e-19]
[x^5] L(s+x) = [-6.6110318108422e-6 +/- 4.51e-20]
[x^6] L(s+x) = [-3.316240908753e-7 +/- 3.85e-20]
[x^7] L(s+x) = [1.0462094584479e-7 +/- 7.78e-21]
cpu/wall(s): 0.003 0.004
virt/peak/res/peak(MB): 26.86 26.88 2.30 2.30
```

Evaluating the Riemann zeta function near the first nontrivial root:

```
> build/examples/lvalue -re 0.5 -im 14.134725
L(s) = [1.76743e-8 +/- 1.93e-14] + [-1.110203e-7 +/- 2.84e-14]*I
cpu/wall(s): 0.001 0.001
virt/peak/res/peak(MB): 26.86 26.88 2.31 2.31

> build/examples/lvalue -z -re 14.134725 -prec 200
Z(s) = [-1.12418349839417533300111494358128257497862927935658e-7 +/- 4.62e-58]
cpu/wall(s): 0.001 0.001
virt/peak/res/peak(MB): 26.86 26.88 2.57 2.57
```

```

## FLOATING-POINT NUMBERS

The radius and midpoint of a ball are represented using two specialized floating-point types.

### 3.1 `mag.h` – fixed-precision unsigned floating-point numbers for bounds

The `mag_t` type is an unsigned floating-point type with a fixed-precision mantissa (30 bits) and an arbitrary-precision exponent (represented as an `fmpz_t`), suited for representing and rigorously manipulating magnitude bounds efficiently. Operations always produce a strict upper or lower bound, but for performance reasons, no attempt is made to compute the best possible bound (in general, a result may be a few ulps larger/smaller than the optimal value). The special values zero and positive infinity are supported (but not NaN). Applications requiring more flexibility (such as correct rounding, or higher precision) should use the `arf_t` type instead.

#### 3.1.1 Types, macros and constants

##### `mag_struct`

A `mag_struct` holds a mantissa and an exponent. Special values are encoded by the mantissa being set to zero.

##### `mag_t`

A `mag_t` is defined as an array of length one of type `mag_struct`, permitting a `mag_t` to be passed by reference.

#### 3.1.2 Memory management

void `mag_init(mag_t x)`

Initializes the variable `x` for use. Its value is set to zero.

void `mag_clear(mag_t x)`

Clears the variable `x`, freeing or recycling its allocated memory.

void `mag_init_set(mag_t x, const mag_t y)`

Initializes `x` and sets it to the value of `y`.

void `mag_swap(mag_t x, mag_t y)`

Swaps `x` and `y` efficiently.

void `mag_set(mag_t x, const mag_t y)`

Sets `x` to the value of `y`.

`mag_ptr` `_mag_vec_init(slong n)`

Allocates a vector of length `n`. All entries are set to zero.

void `_mag_vec_clear(mag_ptr v, slong n)`

Clears a vector of length `n`.

*long* **mag\_allocated\_bytes**(const *mag\_t* *x*)

Returns the total number of bytes heap-allocated internally by this object. The count excludes the size of the structure itself. Add `sizeof(mag_struct)` to get the size of the object as a whole.

### 3.1.3 Special values

void **mag\_zero**(*mag\_t* *x*)

Sets *x* to zero.

void **mag\_one**(*mag\_t* *x*)

Sets *x* to one.

void **mag\_inf**(*mag\_t* *x*)

Sets *x* to positive infinity.

int **mag\_is\_special**(const *mag\_t* *x*)

Returns nonzero iff *x* is zero or positive infinity.

int **mag\_is\_zero**(const *mag\_t* *x*)

Returns nonzero iff *x* is zero.

int **mag\_is\_inf**(const *mag\_t* *x*)

Returns nonzero iff *x* is positive infinity.

int **mag\_is\_finite**(const *mag\_t* *x*)

Returns nonzero iff *x* is not positive infinity (since there is no NaN value, this function is exactly the negation of `mag_is_inf()`).

### 3.1.4 Comparisons

int **mag\_equal**(const *mag\_t* *x*, const *mag\_t* *y*)

Returns nonzero iff *x* and *y* have the same value.

int **mag\_cmp**(const *mag\_t* *x*, const *mag\_t* *y*)

Returns negative, zero, or positive, depending on whether *x* is smaller, equal, or larger than *y*.

int **mag\_cmp\_2exp\_si**(const *mag\_t* *x*, *long* *y*)

Returns negative, zero, or positive, depending on whether *x* is smaller, equal, or larger than  $2^y$ .

void **mag\_min**(*mag\_t* *z*, const *mag\_t* *x*, const *mag\_t* *y*)

void **mag\_max**(*mag\_t* *z*, const *mag\_t* *x*, const *mag\_t* *y*)

Sets *z* respectively to the smaller or the larger of *x* and *y*.

### 3.1.5 Input and output

void **mag\_print**(const *mag\_t* *x*)

Prints *x* to standard output.

void **mag\_fprint**(FILE \* *file*, const *mag\_t* *x*)

Prints *x* to the stream *file*.

### 3.1.6 Random generation

void **mag\_randtest**(*mag\_t* *x*, flint\_rand\_t *state*, *long* *expbits*)

Sets *x* to a random finite value, with an exponent up to *expbits* bits large.

void **mag\_randtest\_special**(*mag\_t* *x*, flint\_rand\_t *state*, *long* *expbits*)

Like `mag_randtest()`, but also sometimes sets *x* to infinity.

### 3.1.7 Conversions

```
void mag_set_d(mag_t y, double x)
void mag_set_fmpr(mag_t y, const fmpr_t x)
void mag_set_ui(mag_t y, ulong x)
void mag_set_fmpz(mag_t y, const fmpz_t x)
    Sets y to an upper bound for  $|x|$ .
void mag_set_d_2exp_fmpz(mag_t z, double x, const fmpz_t y)
void mag_set_fmpz_2exp_fmpz(mag_t z, const fmpz_t x, const fmpz_t y)
void mag_set_ui_2exp_si(mag_t z, ulong x, slong y)
    Sets z to an upper bound for  $|x| \times 2^y$ .
void mag_get_fmpr(fmpr_t y, const mag_t x)
    Sets y exactly to x.
void mag_get_fmpq(fmpq_t y, const mag_t x)
    Sets y exactly to x. Assumes that no overflow occurs.
double mag_get_d(const mag_t x)
    Returns a double giving an upper bound for x.
double mag_get_d_log2_approx(const mag_t x)
    Returns a double approximating  $\log_2(x)$ , suitable for estimating magnitudes (not for rigorous
    bounds). The value is clamped between COEFF_MIN and COEFF_MAX.
void mag_set_ui_lower(mag_t z, ulong x)
void mag_set_fmpz_lower(mag_t z, const fmpz_t x)
    Sets y to a lower bound for  $|x|$ .
void mag_set_fmpz_2exp_fmpz_lower(mag_t z, const fmpz_t x, const fmpz_t y)
    Sets z to a lower bound for  $|x| \times 2^y$ .
```

### 3.1.8 Arithmetic

```
void mag_mul_2exp_si(mag_t z, const mag_t x, slong y)
void mag_mul_2exp_fmpz(mag_t z, const mag_t x, const fmpz_t y)
    Sets z to  $x \times 2^y$ . This operation is exact.
void mag_mul(mag_t z, const mag_t x, const mag_t y)
void mag_mul_ui(mag_t z, const mag_t x, ulong y)
void mag_mul_fmpz(mag_t z, const mag_t x, const fmpz_t y)
    Sets z to an upper bound for  $xy$ .
void mag_add(mag_t z, const mag_t x, const mag_t y)
void mag_add_ui(mag_t z, const mag_t x, ulong y)
    Sets z to an upper bound for  $x + y$ .
void mag_addmul(mag_t z, const mag_t x, const mag_t y)
    Sets z to an upper bound for  $z + xy$ .
void mag_add_2exp_fmpz(mag_t z, const mag_t x, const fmpz_t e)
    Sets z to an upper bound for  $x + 2^e$ .
void mag_add_ui_2exp_si(mag_t z, const mag_t x, ulong y, slong e)
    Sets z to an upper bound for  $x + y2^e$ .
void mag_div(mag_t z, const mag_t x, const mag_t y)
```

```
void mag_div_ui(mag_t z, const mag_t x, ulong y)
void mag_div_fmpz(mag_t z, const mag_t x, const fmpz_t y)
    Sets z to an upper bound for  $x/y$ .
void mag_mul_lower(mag_t z, const mag_t x, const mag_t y)
void mag_mul_ui_lower(mag_t z, const mag_t x, ulong y)
void mag_mul_fmpz_lower(mag_t z, const mag_t x, const fmpz_t y)
    Sets z to a lower bound for  $xy$ .
void mag_add_lower(mag_t z, const mag_t x, const mag_t y)
    Sets z to a lower bound for  $x + y$ .
void mag_sub(mag_t z, const mag_t x, const mag_t y)
    Sets z to an upper bound for  $\max(x - y, 0)$ .
void mag_sub_lower(mag_t z, const mag_t x, const mag_t y)
    Sets z to a lower bound for  $\max(x - y, 0)$ .
```

### 3.1.9 Fast, unsafe arithmetic

The following methods assume that all inputs are finite and that all exponents (in all inputs as well as the final result) fit as *fmpz* inline values. They also assume that the output variables do not have promoted exponents, as they will be overwritten directly (thus leaking memory).

```
void mag_fast_init_set(mag_t x, const mag_t y)
    Initialises x and sets it to the value of y.
void mag_fast_zero(mag_t x)
    Sets x to zero.
int mag_fast_is_zero(const mag_t x)
    Returns nonzero iff x is zero.
void mag_fast_mul(mag_t z, const mag_t x, const mag_t y)
    Sets z to an upper bound for  $xy$ .
void mag_fast_addmul(mag_t z, const mag_t x, const mag_t y)
    Sets z to an upper bound for  $z + xy$ .
void mag_fast_add_2exp_si(mag_t z, const mag_t x, slong e)
    Sets z to an upper bound for  $x + 2^e$ .
void mag_fast_mul_2exp_si(mag_t z, const mag_t x, slong e)
    Sets z to an upper bound for  $x2^e$ .
```

### 3.1.10 Powers and logarithms

```
void mag_pow_ui(mag_t z, const mag_t x, ulong e)
void mag_pow_fmpz(mag_t z, const mag_t x, const fmpz_t e)
    Sets z to an upper bound for  $x^e$ . Requires  $e \geq 0$ .
void mag_pow_ui_lower(mag_t z, const mag_t x, ulong e)
    Sets z to a lower bound for  $x^e$ .
void mag_sqrt(mag_t z, const mag_t x)
    Sets z to an upper bound for  $\sqrt{x}$ .
void mag_rsqrtd(mag_t z, const mag_t x)
    Sets z to an upper bound for  $1/\sqrt{x}$ .
void mag_hypot(mag_t z, const mag_t x, const mag_t y)
    Sets z to an upper bound for  $\sqrt{x^2 + y^2}$ .
```

void **mag\_root**(*mag\_t* z, const *mag\_t* x, *ulong* n)  
 Sets *z* to an upper bound for  $x^{1/n}$ . We evaluate  $\exp(\log(1 + 2^{kn}x)/n)2^{-k}$ , where *k* is chosen so that  $2^{kn}x \approx 2^{30}$ .

void **mag\_log1p**(*mag\_t* z, const *mag\_t* x)  
 Sets *z* to an upper bound for  $\log(1 + x)$ . The bound is computed accurately for small *x*.

void **mag\_log\_ui**(*mag\_t* z, *ulong* n)  
 Sets *z* to an upper bound for  $\log(n)$ .

void **mag\_exp**(*mag\_t* z, const *mag\_t* x)  
 Sets *z* to an upper bound for  $\exp(x)$ .

void **mag\_expinv**(*mag\_t* z, const *mag\_t* x)  
 Sets *z* to an upper bound for  $\exp(-x)$ . As currently implemented, the bound is computed crudely by rounding *x* down to an integer before approximating the exponential.

void **mag\_expm1**(*mag\_t* z, const *mag\_t* x)  
 Sets *z* to an upper bound for  $\exp(x) - 1$ . The bound is computed accurately for small *x*.

void **mag\_exp\_tail**(*mag\_t* z, const *mag\_t* x, *ulong* N)  
 Sets *z* to an upper bound for  $\sum_{k=N}^{\infty} x^k/k!$ .

void **mag\_binpow\_uiui**(*mag\_t* z, *ulong* m, *ulong* n)  
 Sets *z* to an upper bound for  $(1 + 1/m)^n$ .

void **mag\_geom\_series**(*mag\_t* res, const *mag\_t* x, *ulong* N)  
 Sets *res* to an upper bound for  $\sum_{k=N}^{\infty} x^k$ .

### 3.1.11 Special functions

void **mag\_const\_pi**(*mag\_t* z)  
 Sets *z* to an upper bound for  $\pi$ .

void **mag\_fac\_ui**(*mag\_t* z, *ulong* n)  
 Sets *z* to an upper bound for  $n!$ .

void **mag\_rfac\_ui**(*mag\_t* z, *ulong* n)  
 Sets *z* to an upper bound for  $1/n!$ .

void **mag\_bernoulli\_div\_fac\_ui**(*mag\_t* z, *ulong* n)  
 Sets *z* to an upper bound for  $|B_n|/n!$  where  $B_n$  denotes a Bernoulli number.

void **mag\_polylog\_tail**(*mag\_t* u, const *mag\_t* z, *slong* s, *ulong* d, *ulong* N)  
 Sets *u* to an upper bound for

$$\sum_{k=N}^{\infty} \frac{z^k \log^d(k)}{k^s}.$$

Note: in applications where *s* in this formula may be real or complex, the user can simply substitute any convenient integer  $s'$  such that  $s' \leq \operatorname{Re}(s)$ .

Denote the terms by  $T(k)$ . We pick a nonincreasing function  $U(k)$  such that

$$\frac{T(k+1)}{T(k)} = z \left( \frac{k}{k+1} \right)^s \left( \frac{\log(k+1)}{\log(k)} \right)^d \leq U(k).$$

Then, as soon as  $U(N) < 1$ ,

$$\sum_{k=N}^{\infty} T(k) \leq T(N) \sum_{k=0}^{\infty} U(N)^k = \frac{T(N)}{1 - U(N)}.$$

In particular, we take

$$U(k) = z B(k, \max(0, -s)) B(k \log(k), d)$$

where  $B(m, n) = (1 + 1/m)^n$ . This follows from the bounds

$$\left(\frac{k}{k+1}\right)^s \leq \begin{cases} 1 & \text{if } s \geq 0 \\ (1 + 1/k)^{-s} & \text{if } s < 0. \end{cases}$$

and

$$\left(\frac{\log(k+1)}{\log(k)}\right)^d \leq \left(1 + \frac{1}{k \log(k)}\right)^d.$$

void **mag\_hurwitz\_zeta\_uiui**(*mag\_t* res, *ulong* s, *ulong* a)

Sets *res* to an upper bound for  $\zeta(s, a) = \sum_{k=0}^{\infty} (k+a)^{-s}$ . We use the formula

$$\zeta(s, a) \leq \frac{1}{a^s} + \frac{1}{(s-1)a^{s-1}}$$

which is obtained by estimating the sum by an integral. If  $s \leq 1$  or  $a = 0$ , the bound is infinite.

## 3.2 arf.h – arbitrary-precision floating-point numbers

A variable of type *arf\_t* holds an arbitrary-precision binary floating-point number, i.e. a rational number of the form  $x \times 2^y$  where  $x, y \in \mathbb{Z}$  and  $x$  is odd; or one of the special values zero, plus infinity, minus infinity, or NaN (not-a-number).

The *exponent* of a finite and nonzero floating-point number can be defined in different ways: for example, as the component  $y$  above, or as the unique integer  $e$  such that  $x \times 2^y = m \times 2^e$  where  $1/2 \leq |m| < 1$ . The internal representation of an *arf\_t* stores the exponent in the latter format.

The conventions for special values largely follow those of the IEEE floating-point standard. At the moment, there is no support for negative zero, unsigned infinity, or a NaN with a payload, though some of these might be added in the future.

Except where otherwise noted, the output of an operation is the floating-point number obtained by taking the inputs as exact numbers, in principle carrying out the operation exactly, and rounding the resulting real number to the nearest representable floating-point number whose mantissa has at most the specified number of bits, in the specified direction of rounding. Some operations are always or optionally done exactly.

The *arf\_t* type is almost identical semantically to the legacy *fmpz\_t* type, but uses a more efficient internal representation. The most significant differences that the user has to be aware of are:

- The mantissa is no longer represented as a FLINT *fmpz*, and the internal exponent points to the top of the binary expansion of the mantissa instead of of the bottom. Code designed to manipulate components of an *fmpz\_t* directly can be ported to the *arf\_t* type by making use of *arf\_get\_fmpz\_2exp()* and *arf\_set\_fmpz\_2exp()*.
- Some *arf\_t* functions return an *int* indicating whether a result is inexact, whereas the corresponding *fmpz\_t* functions return an *slong* encoding the relative exponent of the error.

### 3.2.1 Types, macros and constants

**arf\_struct**

**arf\_t**

An *arf\_struct* contains four words: an *fmpz* exponent (*exp*), a *size* field tracking the number of limbs used (one bit of this field is also used for the sign of the number), and two more words. The last two words hold the value directly if there are at most two limbs, and otherwise contain one *alloc* field (tracking the total number of allocated limbs, not all of which might be used) and a pointer to the actual limbs. Thus, up to 128 bits on a 64-bit machine and 64 bits on a 32-bit machine, no space outside of the *arf\_struct* is used.

An *arf\_t* is defined as an array of length one of type *arf\_struct*, permitting an *arf\_t* to be passed by reference.

#### **arf\_rnd\_t**

Specifies the rounding mode for the result of an approximate operation.

#### **ARF\_RND\_DOWN**

Specifies that the result of an operation should be rounded to the nearest representable number in the direction towards zero.

#### **ARF\_RND\_UP**

Specifies that the result of an operation should be rounded to the nearest representable number in the direction away from zero.

#### **ARF\_RND\_FLOOR**

Specifies that the result of an operation should be rounded to the nearest representable number in the direction towards minus infinity.

#### **ARF\_RND\_CEIL**

Specifies that the result of an operation should be rounded to the nearest representable number in the direction towards plus infinity.

#### **ARF\_RND\_NEAR**

Specifies that the result of an operation should be rounded to the nearest representable number, rounding to even if there is a tie between two values.

#### **ARF\_PREC\_EXACT**

If passed as the precision parameter to a function, indicates that no rounding is to be performed.

**Warning:** use of this value is unsafe in general. It must only be passed as input under the following two conditions:

- The operation in question can inherently be viewed as an exact operation in  $\mathbb{Z}[\frac{1}{2}]$  for all possible inputs, provided that the precision is large enough. Examples include addition, multiplication, conversion from integer types to arbitrary-precision floating-point types, and evaluation of some integer-valued functions.
- The exact result of the operation will certainly fit in memory. Note that, for example, adding two numbers whose exponents are far apart can easily produce an exact result that is far too large to store in memory.

The typical use case is to work with small integer values, double precision constants, and the like. It is also useful when writing test code. If in doubt, simply try with some convenient high precision instead of using this special value, and check that the result is exact.

## 3.2.2 Memory management

void **arf\_init**(*arf\_t* *x*)

Initializes the variable *x* for use. Its value is set to zero.

void **arf\_clear**(*arf\_t* *x*)

Clears the variable *x*, freeing or recycling its allocated memory.

slong **arf\_allocated\_bytes**(const *arf\_t* *x*)

Returns the total number of bytes heap-allocated internally by this object. The count excludes the size of the structure itself. Add `sizeof(arf_struct)` to get the size of the object as a whole.

## 3.2.3 Special values

void **arf\_zero**(*arf\_t* *x*)

void **arf\_one**(*arf\_t* *x*)

void **arf\_pos\_inf**(*arf\_t* *x*)

```
void arf_neg_inf(arf_t x)
void arf_nan(arf_t x)
    Sets  $x$  respectively to 0, 1,  $+\infty$ ,  $-\infty$ , NaN.
int arf_is_zero(const arf_t x)
int arf_is_one(const arf_t x)
int arf_is_pos_inf(const arf_t x)
int arf_is_neg_inf(const arf_t x)
int arf_is_nan(const arf_t x)
    Returns nonzero iff  $x$  respectively equals 0, 1,  $+\infty$ ,  $-\infty$ , NaN.
int arf_is_inf(const arf_t x)
    Returns nonzero iff  $x$  equals either  $+\infty$  or  $-\infty$ .
int arf_is_normal(const arf_t x)
    Returns nonzero iff  $x$  is a finite, nonzero floating-point value, i.e. not one of the special values 0,  $+\infty$ ,  $-\infty$ , NaN.
int arf_is_special(const arf_t x)
    Returns nonzero iff  $x$  is one of the special values 0,  $+\infty$ ,  $-\infty$ , NaN, i.e. not a finite, nonzero floating-point value.
int arf_is_finite(arf_t x)
    Returns nonzero iff  $x$  is a finite floating-point value, i.e. not one of the values  $+\infty$ ,  $-\infty$ , NaN.
    (Note that this is not equivalent to the negation of arf_is_inf() .)
```

### 3.2.4 Assignment, rounding and conversions

```
void arf_set(arf_t y, const arf_t x)
void arf_set_mpz(arf_t y, const mpz_t x)
void arf_set_fmpz(arf_t y, const fmpz_t x)
void arf_set_ui(arf_t y, ulong x)
void arf_set_si(arf_t y, slong x)
void arf_set_mpfr(arf_t y, const mpfr_t x)
void arf_set_fmpr(arf_t y, const fmpr_t x)
void arf_set_d(arf_t y, double x)
    Sets  $y$  exactly to  $x$ .
void arf_swap(arf_t y, arf_t x)
    Swaps  $y$  and  $x$  efficiently.
void arf_init_set_ui(arf_t y, ulong x)
void arf_init_set_si(arf_t y, slong x)
    Initialises  $y$  and sets it to  $x$  in a single operation.
int arf_set_round(arf_t y, const arf_t x, slong prec, arf_rnd_t rnd)
int arf_set_round_si(arf_t x, slong v, slong prec, arf_rnd_t rnd)
int arf_set_round_ui(arf_t x, ulong v, slong prec, arf_rnd_t rnd)
int arf_set_round_mpz(arf_t y, const mpz_t x, slong prec, arf_rnd_t rnd)
int arf_set_round_fmpz(arf_t y, const fmpz_t x, slong prec, arf_rnd_t rnd)
    Sets  $y$  to  $x$ , rounded to  $prec$  bits in the direction specified by  $rnd$ .
void arf_set_si_2exp_si(arf_t y, slong m, slong e)
```

---

```
void arf_set_ui_2exp_si(arf_t y, ulong m, slong e)
```

```
void arf_set_fmpz_2exp(arf_t y, const fmpz_t m, const fmpz_t e)
```

Sets  $y$  to  $m \times 2^e$ .

```
int arf_set_round_fmpz_2exp(arf_t y, const fmpz_t x, const fmpz_t e, slong prec,
                           arf_rnd_t rnd)
```

Sets  $y$  to  $x \times 2^e$ , rounded to  $prec$  bits in the direction specified by  $rnd$ .

```
void arf_get_fmpz_2exp(fmpz_t m, fmpz_t e, const arf_t x)
```

Sets  $m$  and  $e$  to the unique integers such that  $x = m \times 2^e$  and  $m$  is odd, provided that  $x$  is a nonzero finite fraction. If  $x$  is zero, both  $m$  and  $e$  are set to zero. If  $x$  is infinite or NaN, the result is undefined.

```
void arf_frexp(arf_t m, fmpz_t e, const arf_t x)
```

Writes  $x$  as  $m \times 2^e$ , where  $1/2 \leq |m| < 1$  if  $x$  is a normal value. If  $x$  is a special value, copies this to  $m$  and sets  $e$  to zero. Note: for the inverse operation (*ldexp*), use `arf_mul_2exp_fmpz()`.

```
double arf_get_d(const arf_t x, arf_rnd_t rnd)
```

Returns  $x$  rounded to a double in the direction specified by  $rnd$ . This method rounds correctly when overflowing or underflowing the double exponent range (this was not the case in an earlier version).

```
void arf_get_fmpr(fmpr_t y, const arf_t x)
```

Sets  $y$  exactly to  $x$ .

```
int arf_get_mpfr(mpfr_t y, const arf_t x, mpfr_rnd_t rnd)
```

Sets the MPFR variable  $y$  to the value of  $x$ . If the precision of  $x$  is too small to allow  $y$  to be represented exactly, it is rounded in the specified MPFR rounding mode. The return value (-1, 0 or 1) indicates the direction of rounding, following the convention of the MPFR library.

```
int arf_get_fmpz(fmpz_t z, const arf_t x, arf_rnd_t rnd)
```

Sets  $z$  to  $x$  rounded to the nearest integer in the direction specified by  $rnd$ . If  $rnd$  is `ARF_RND_NEAR`, rounds to the nearest even integer in case of a tie. Returns inexact (beware: accordingly returns whether  $x$  is *not* an integer).

This method aborts if  $x$  is infinite or NaN, or if the exponent of  $x$  is so large that allocating memory for the result fails.

Warning: this method will allocate a huge amount of memory to store the result if the exponent of  $x$  is huge. Memory allocation could succeed even if the required space is far larger than the physical memory available on the machine, resulting in swapping. It is recommended to check that  $x$  is within a reasonable range before calling this method.

```
slong arf_get_si(const arf_t x, arf_rnd_t rnd)
```

Returns  $x$  rounded to the nearest integer in the direction specified by  $rnd$ . If  $rnd$  is `ARF_RND_NEAR`, rounds to the nearest even integer in case of a tie. Aborts if  $x$  is infinite, NaN, or the value is too large to fit in a slong.

```
int arf_get_fmpz_fixed_fmpz(fmpz_t y, const arf_t x, const fmpz_t e)
```

```
int arf_get_fmpz_fixed_si(fmpz_t y, const arf_t x, slong e)
```

Converts  $x$  to a mantissa with predetermined exponent, i.e. computes an integer  $y$  such that  $y \times 2^e \approx x$ , truncating if necessary. Returns 0 if exact and 1 if truncation occurred.

The warnings for `arf_get_fmpz()` apply.

```
void arf_floor(arf_t y, const arf_t x)
```

```
void arf_ceil(arf_t y, const arf_t x)
```

Sets  $y$  to  $\lfloor x \rfloor$  and  $\lceil x \rceil$  respectively. The result is always represented exactly, requiring no more bits to store than the input. To round the result to a floating-point number with a lower precision, call `arf_set_round()` afterwards.

### 3.2.5 Comparisons and bounds

int **arf\_equal**(const *arf\_t* x, const *arf\_t* y)

int **arf\_equal\_si**(const *arf\_t* x, *slong* y)

Returns nonzero iff  $x$  and  $y$  are exactly equal. This function does not treat NaN specially, i.e. NaN compares as equal to itself.

int **arf\_cmp**(const *arf\_t* x, const *arf\_t* y)

int **arf\_cmp\_si**(const *arf\_t* x, *slong* y)

int **arf\_cmp\_ui**(const *arf\_t* x, *ulong* y)

int **arf\_cmp\_d**(const *arf\_t* x, double y)

Returns negative, zero, or positive, depending on whether  $x$  is respectively smaller, equal, or greater compared to  $y$ . Comparison with NaN is undefined.

int **arf\_cmpabs**(const *arf\_t* x, const *arf\_t* y)

int **arf\_cmpabs\_ui**(const *arf\_t* x, *ulong* y)

int **arf\_cmpabs\_d**(const *arf\_t* x, *ulong* y)

int **arf\_cmpabs\_mag**(const *arf\_t* x, const *mag\_t* y)

Compares the absolute values of  $x$  and  $y$ .

int **arf\_cmp\_2exp\_si**(const *arf\_t* x, *slong* e)

int **arf\_cmpabs\_2exp\_si**(const *arf\_t* x, *slong* e)

Compares  $x$  (respectively its absolute value) with  $2^e$ .

int **arf\_sgn**(const *arf\_t* x)

Returns  $-1$ ,  $0$  or  $+1$  according to the sign of  $x$ . The sign of NaN is undefined.

void **arf\_min**(*arf\_t* z, const *arf\_t* a, const *arf\_t* b)

void **arf\_max**(*arf\_t* z, const *arf\_t* a, const *arf\_t* b)

Sets  $z$  respectively to the minimum and the maximum of  $a$  and  $b$ .

*slong* **arf\_bits**(const *arf\_t* x)

Returns the number of bits needed to represent the absolute value of the mantissa of  $x$ , i.e. the minimum precision sufficient to represent  $x$  exactly. Returns  $0$  if  $x$  is a special value.

int **arf\_is\_int**(const *arf\_t* x)

Returns nonzero iff  $x$  is integer-valued.

int **arf\_is\_int\_2exp\_si**(const *arf\_t* x, *slong* e)

Returns nonzero iff  $x$  equals  $n2^e$  for some integer  $n$ .

void **arf\_abs\_bound\_lt\_2exp\_fmpz**(*fmpz\_t* b, const *arf\_t* x)

Sets  $b$  to the smallest integer such that  $|x| < 2^b$ . If  $x$  is zero, infinity or NaN, the result is undefined.

void **arf\_abs\_bound\_le\_2exp\_fmpz**(*fmpz\_t* b, const *arf\_t* x)

Sets  $b$  to the smallest integer such that  $|x| \leq 2^b$ . If  $x$  is zero, infinity or NaN, the result is undefined.

*slong* **arf\_abs\_bound\_lt\_2exp\_si**(const *arf\_t* x)

Returns the smallest integer  $b$  such that  $|x| < 2^b$ , clamping the result to lie between  $-ARF\_PREC\_EXACT$  and  $ARF\_PREC\_EXACT$  inclusive. If  $x$  is zero,  $-ARF\_PREC\_EXACT$  is returned, and if  $x$  is infinity or NaN,  $ARF\_PREC\_EXACT$  is returned.

### 3.2.6 Magnitude functions

void **arf\_get\_mag**(*mag\_t* y, const *arf\_t* x)

Sets  $y$  to an upper bound for the absolute value of  $x$ .

void **arf\_get\_mag\_lower**(*mag\_t* y, const *arf\_t* x)

Sets  $y$  to a lower bound for the absolute value of  $x$ .

---

```
void arf_set_mag(arf_t y, const mag_t x)
    Sets y to x.
```

```
void mag_init_set_arf(mag_t y, const arf_t x)
    Initializes y and sets it to an upper bound for x.
```

```
void mag_fast_init_set_arf(mag_t y, const arf_t x)
    Initializes y and sets it to an upper bound for x. Assumes that the exponent of y is small.
```

```
void arf_mag_set_ulp(mag_t z, const arf_t y, slong prec)
    Sets z to the magnitude of the unit in the last place (ulp) of y at precision prec.
```

```
void arf_mag_add_ulp(mag_t z, const mag_t x, const arf_t y, slong prec)
    Sets z to an upper bound for the sum of x and the magnitude of the unit in the last place (ulp) of y at precision prec.
```

```
void arf_mag_fast_add_ulp(mag_t z, const mag_t x, const arf_t y, slong prec)
    Sets z to an upper bound for the sum of x and the magnitude of the unit in the last place (ulp) of y at precision prec. Assumes that all exponents are small.
```

### 3.2.7 Shallow assignment

```
void arf_init_set_shallow(arf_t z, const arf_t x)
```

```
void arf_init_set_mag_shallow(arf_t z, const mag_t x)
    Initializes z to a shallow copy of x. A shallow copy just involves copying struct data (no heap allocation is performed).
```

The target variable *z* may not be cleared or modified in any way (it can only be used as constant input to functions), and may not be used after *x* has been cleared. Moreover, after *x* has been assigned shallowly to *z*, no modification of *x* is permitted as long as *z* is in use.

```
void arf_init_neg_shallow(arf_t z, const arf_t x)
```

```
void arf_init_neg_mag_shallow(arf_t z, const mag_t x)
    Initializes z shallowly to the negation of x.
```

### 3.2.8 Random number generation

```
void arf_randtest(arf_t x, flint_rand_t state, slong bits, slong mag_bits)
    Generates a finite random number whose mantissa has precision at most bits and whose exponent has at most mag_bits bits. The values are distributed non-uniformly: special bit patterns are generated with high probability in order to allow the test code to exercise corner cases.
```

```
void arf_randtest_not_zero(arf_t x, flint_rand_t state, slong bits, slong mag_bits)
    Identical to arf_randtest(), except that zero is never produced as an output.
```

```
void arf_randtest_special(arf_t x, flint_rand_t state, slong bits, slong mag_bits)
    Identical to arf_randtest(), except that the output occasionally is set to an infinity or NaN.
```

### 3.2.9 Input and output

```
void arf_debug(const arf_t x)
    Prints information about the internal representation of x.
```

```
void arf_print(const arf_t x)
    Prints x as an integer mantissa and exponent.
```

```
void arf_printd(const arf_t y, slong d)
    Prints x as a decimal floating-point number, rounding to d digits. This function is currently implemented using MPFR, and does not support large exponents.
```

void **arf\_fprint**(FILE \* *file*, const *arf\_t* *x*)

Prints *x* as an integer mantissa and exponent to the stream *file*.

void **arf\_fprintd**(FILE \* *file*, const *arf\_t* *y*, *slong* *d*)

Prints *x* as a decimal floating-point number to the stream *file*, rounding to *d* digits. This function is currently implemented using MPFR, and does not support large exponents.

### 3.2.10 Addition and multiplication

void **arf\_abs**(*arf\_t* *y*, const *arf\_t* *x*)

Sets *y* to the absolute value of *x*.

void **arf\_neg**(*arf\_t* *y*, const *arf\_t* *x*)

Sets  $y = -x$  exactly.

int **arf\_neg\_round**(*arf\_t* *y*, const *arf\_t* *x*, *slong* *prec*, *arf\_rnd\_t* *rnd*)

Sets  $y = -x$ , rounded to *prec* bits in the direction specified by *rnd*, returning nonzero iff the operation is inexact.

void **arf\_mul\_2exp\_si**(*arf\_t* *y*, const *arf\_t* *x*, *slong* *e*)

void **arf\_mul\_2exp\_fmpz**(*arf\_t* *y*, const *arf\_t* *x*, const *fmpz\_t* *e*)

Sets  $y = x2^e$  exactly.

int **arf\_mul**(*arf\_t* *z*, const *arf\_t* *x*, const *arf\_t* *y*, *slong* *prec*, *arf\_rnd\_t* *rnd*)

int **arf\_mul\_ui**(*arf\_t* *z*, const *arf\_t* *x*, *ulong* *y*, *slong* *prec*, *arf\_rnd\_t* *rnd*)

int **arf\_mul\_si**(*arf\_t* *z*, const *arf\_t* *x*, *slong* *y*, *slong* *prec*, *arf\_rnd\_t* *rnd*)

int **arf\_mul\_mpz**(*arf\_t* *z*, const *arf\_t* *x*, const *mpz\_t* *y*, *slong* *prec*, *arf\_rnd\_t* *rnd*)

int **arf\_mul\_fmpz**(*arf\_t* *z*, const *arf\_t* *x*, const *fmpz\_t* *y*, *slong* *prec*, *arf\_rnd\_t* *rnd*)

Sets  $z = x \times y$ , rounded to *prec* bits in the direction specified by *rnd*, returning nonzero iff the operation is inexact.

int **arf\_add**(*arf\_t* *z*, const *arf\_t* *x*, const *arf\_t* *y*, *slong* *prec*, *arf\_rnd\_t* *rnd*)

int **arf\_add\_si**(*arf\_t* *z*, const *arf\_t* *x*, *slong* *y*, *slong* *prec*, *arf\_rnd\_t* *rnd*)

int **arf\_add\_ui**(*arf\_t* *z*, const *arf\_t* *x*, *ulong* *y*, *slong* *prec*, *arf\_rnd\_t* *rnd*)

int **arf\_add\_fmpz**(*arf\_t* *z*, const *arf\_t* *x*, const *fmpz\_t* *y*, *slong* *prec*, *arf\_rnd\_t* *rnd*)

Sets  $z = x + y$ , rounded to *prec* bits in the direction specified by *rnd*, returning nonzero iff the operation is inexact.

int **arf\_add\_fmpz\_2exp**(*arf\_t* *z*, const *arf\_t* *x*, const *fmpz\_t* *y*, const *fmpz\_t* *e*, *slong* *prec*, *arf\_rnd\_t* *rnd*)

Sets  $z = x + y2^e$ , rounded to *prec* bits in the direction specified by *rnd*, returning nonzero iff the operation is inexact.

int **arf\_sub**(*arf\_t* *z*, const *arf\_t* *x*, const *arf\_t* *y*, *slong* *prec*, *arf\_rnd\_t* *rnd*)

int **arf\_sub\_si**(*arf\_t* *z*, const *arf\_t* *x*, *slong* *y*, *slong* *prec*, *arf\_rnd\_t* *rnd*)

int **arf\_sub\_ui**(*arf\_t* *z*, const *arf\_t* *x*, *ulong* *y*, *slong* *prec*, *arf\_rnd\_t* *rnd*)

int **arf\_sub\_fmpz**(*arf\_t* *z*, const *arf\_t* *x*, const *fmpz\_t* *y*, *slong* *prec*, *arf\_rnd\_t* *rnd*)

Sets  $z = x - y$ , rounded to *prec* bits in the direction specified by *rnd*, returning nonzero iff the operation is inexact.

int **arf\_addmul**(*arf\_t* *z*, const *arf\_t* *x*, const *arf\_t* *y*, *slong* *prec*, *arf\_rnd\_t* *rnd*)

int **arf\_addmul\_ui**(*arf\_t* *z*, const *arf\_t* *x*, *ulong* *y*, *slong* *prec*, *arf\_rnd\_t* *rnd*)

int **arf\_addmul\_si**(*arf\_t* *z*, const *arf\_t* *x*, *slong* *y*, *slong* *prec*, *arf\_rnd\_t* *rnd*)

int **arf\_addmul\_mpz**(*arf\_t* *z*, const *arf\_t* *x*, const *mpz\_t* *y*, *slong* *prec*, *arf\_rnd\_t* *rnd*)

int **arf\_addmul\_fmpz**(arf\_t z, const arf\_t x, const fmpz\_t y, slong prec, arf\_rnd\_t rnd)  
 Sets  $z = z + x \times y$ , rounded to *prec* bits in the direction specified by *rnd*, returning nonzero iff the operation is inexact.

int **arf\_submul**(arf\_t z, const arf\_t x, const arf\_t y, slong prec, arf\_rnd\_t rnd)

int **arf\_submul\_ui**(arf\_t z, const arf\_t x, ulong y, slong prec, arf\_rnd\_t rnd)

int **arf\_submul\_si**(arf\_t z, const arf\_t x, slong y, slong prec, arf\_rnd\_t rnd)

int **arf\_submul\_mpz**(arf\_t z, const arf\_t x, const mpz\_t y, slong prec, arf\_rnd\_t rnd)

int **arf\_submul\_fmpz**(arf\_t z, const arf\_t x, const fmpz\_t y, slong prec, arf\_rnd\_t rnd)  
 Sets  $z = z - x \times y$ , rounded to *prec* bits in the direction specified by *rnd*, returning nonzero iff the operation is inexact.

int **arf\_sosq**(arf\_t z, const arf\_t x, const arf\_t y, slong prec, arf\_rnd\_t rnd)  
 Sets  $z = x^2 + y^2$ , rounded to *prec* bits in the direction specified by *rnd*, returning nonzero iff the operation is inexact.

### 3.2.11 Summation

int **arf\_sum**(arf\_t s, arf\_srcptr terms, slong len, slong prec, arf\_rnd\_t rnd)  
 Sets *s* to the sum of the array *terms* of length *len*, rounded to *prec* bits in the direction specified by *rnd*. The sum is computed as if done without any intermediate rounding error, with only a single rounding applied to the final result. Unlike repeated calls to **arf\_add()** with infinite precision, this function does not overflow if the magnitudes of the terms are far apart. Warning: this function is implemented naively, and the running time is quadratic with respect to *len* in the worst case.

### 3.2.12 Division

int **arf\_div**(arf\_t z, const arf\_t x, const arf\_t y, slong prec, arf\_rnd\_t rnd)

int **arf\_div\_ui**(arf\_t z, const arf\_t x, ulong y, slong prec, arf\_rnd\_t rnd)

int **arf\_ui\_div**(arf\_t z, ulong x, const arf\_t y, slong prec, arf\_rnd\_t rnd)

int **arf\_div\_si**(arf\_t z, const arf\_t x, slong y, slong prec, arf\_rnd\_t rnd)

int **arf\_si\_div**(arf\_t z, slong x, const arf\_t y, slong prec, arf\_rnd\_t rnd)

int **arf\_div\_fmpz**(arf\_t z, const arf\_t x, const fmpz\_t y, slong prec, arf\_rnd\_t rnd)

int **arf\_fmpz\_div**(arf\_t z, const fmpz\_t x, const arf\_t y, slong prec, arf\_rnd\_t rnd)

int **arf\_fmpz\_div\_fmpz**(arf\_t z, const fmpz\_t x, const fmpz\_t y, slong prec, arf\_rnd\_t rnd)  
 Sets  $z = x/y$ , rounded to *prec* bits in the direction specified by *rnd*, returning nonzero iff the operation is inexact. The result is NaN if *y* is zero.

### 3.2.13 Square roots

int **arf\_sqrt**(arf\_t z, const arf\_t x, slong prec, arf\_rnd\_t rnd)

int **arf\_sqrt\_ui**(arf\_t z, ulong x, slong prec, arf\_rnd\_t rnd)

int **arf\_sqrt\_fmpz**(arf\_t z, const fmpz\_t x, slong prec, arf\_rnd\_t rnd)  
 Sets  $z = \sqrt{x}$ , rounded to *prec* bits in the direction specified by *rnd*, returning nonzero iff the operation is inexact. The result is NaN if *x* is negative.

int **arf\_rsqrt**(arf\_t z, const arf\_t x, slong prec, arf\_rnd\_t rnd)  
 Sets  $z = 1/\sqrt{x}$ , rounded to *prec* bits in the direction specified by *rnd*, returning nonzero iff the operation is inexact. The result is NaN if *x* is negative, and  $+\infty$  if *x* is zero.

int **arf\_root**(arf\_t z, const arf\_t x, ulong k, slong prec, arf\_rnd\_t rnd)

Sets  $z = x^{1/k}$ , rounded to *prec* bits in the direction specified by *rnd*, returning nonzero iff the operation is inexact. The result is NaN if *x* is negative. Warning: this function is a wrapper around the MPFR root function. It gets slow and uses much memory for large *k*.

### 3.2.14 Complex arithmetic

int **arf\_complex\_mul**(arf\_t e, arf\_t f, const arf\_t a, const arf\_t b, const arf\_t c, const arf\_t d, slong prec, arf\_rnd\_t rnd)

int **arf\_complex\_mul\_fallback**(arf\_t e, arf\_t f, const arf\_t a, const arf\_t b, const arf\_t c, const arf\_t d, slong prec, arf\_rnd\_t rnd)

Computes the complex product  $e + fi = (a + bi)(c + di)$ , rounding both *e* and *f* correctly to *prec* bits in the direction specified by *rnd*. The first bit in the return code indicates inexactness of *e*, and the second bit indicates inexactness of *f*.

If any of the components *a*, *b*, *c*, *d* is zero, two real multiplications and no additions are done. This convention is used even if any other part contains an infinity or NaN, and the behavior with infinite/NaN input is defined accordingly.

The *fallback* version is implemented naively, for testing purposes. No squaring optimization is implemented.

int **arf\_complex\_sqr**(arf\_t e, arf\_t f, const arf\_t a, const arf\_t b, slong prec, arf\_rnd\_t rnd)

Computes the complex square  $e + fi = (a + bi)^2$ . This function has identical semantics to **arf\_complex\_mul()** (with *c* = *a*, *b* = *d*), but is faster.

### 3.2.15 Low-level methods

int **\_arf\_get\_integer\_mpn**(mp\_ptr y, mp\_srcptr xp, mp\_size\_t xn, slong exp)

Given a floating-point number *x* represented by *xn* limbs at *xp* and an exponent *exp*, writes the integer part of *x* to *y*, returning whether the result is inexact. The correct number of limbs is written (no limbs are written if the integer part of *x* is zero). Assumes that *xp*[0] is nonzero and that the top bit of *xp*[*xn*-1] is set.

int **\_arf\_set\_mpn\_fixed**(arf\_t z, mp\_srcptr xp, mp\_size\_t xn, mp\_size\_t fixn, int negative, slong prec, arf\_rnd\_t rnd)

Sets *z* to the fixed-point number having *xn* total limbs and *fixn* fractional limbs, negated if *negative* is set, rounding *z* to *prec* bits in the direction *rnd* and returning whether the result is inexact. Both *xn* and *fixn* must be nonnegative and not so large that the bit shift would overflow an *slong*, but otherwise no assumptions are made about the input.

int **\_arf\_set\_round\_ui**(arf\_t z, ulong x, int sgnbit, slong prec, arf\_rnd\_t rnd)

Sets *z* to the integer *x*, negated if *sgnbit* is 1, rounded to *prec* bits in the direction specified by *rnd*. There are no assumptions on *x*.

int **\_arf\_set\_round\_uiui**(arf\_t z, slong \* fix, mp\_limb\_t hi, mp\_limb\_t lo, int sgnbit, slong prec, arf\_rnd\_t rnd)

Sets the mantissa of *z* to the two-limb mantissa given by *hi* and *lo*, negated if *sgnbit* is 1, rounded to *prec* bits in the direction specified by *rnd*. Requires that not both *hi* and *lo* are zero. Writes the exponent shift to *fix* without writing the exponent of *z* directly.

int **\_arf\_set\_round\_mpn**(arf\_t z, slong \* exp\_shift, mp\_srcptr x, mp\_size\_t xn, int sgnbit, slong prec, arf\_rnd\_t rnd)

Sets the mantissa of *z* to the mantissa given by the *xn* limbs in *x*, negated if *sgnbit* is 1, rounded to *prec* bits in the direction specified by *rnd*. Returns the inexact flag. Requires that *xn* is positive and that the top limb of *x* is nonzero. If *x* has leading zero bits, writes the shift to *exp\_shift*. This method does not write the exponent of *z* directly. Requires that *x* does not point to the limbs of *z*.

## REAL AND COMPLEX NUMBERS

Real numbers (*arb\_t*) are represented as midpoint-radius intervals, also known as balls. Complex numbers (*acb\_t*) are represented in rectangular form, with balls for the real and imaginary parts.

### 4.1 *arb.h* – real numbers

An *arb\_t* represents a ball over the real numbers, that is, an interval  $[m \pm r] \equiv [m - r, m + r]$  where the midpoint  $m$  and the radius  $r$  are (extended) real numbers and  $r$  is nonnegative (possibly infinite). The result of an (approximate) operation done on *arb\_t* variables is a ball which contains the result of the (mathematically exact) operation applied to any choice of points in the input balls. In general, the output ball is not the smallest possible.

The precision parameter passed to each function roughly indicates the precision to which calculations on the midpoint are carried out (operations on the radius are always done using a fixed, small precision.)

For arithmetic operations, the precision parameter currently simply specifies the precision of the corresponding *arf\_t* operation. In the future, the arithmetic might be made faster by incorporating sloppy rounding (typically equivalent to a loss of 1-2 bits of effective working precision) when the result is known to be inexact (while still propagating errors rigorously, of course). Arithmetic operations done on exact input with exactly representable output are always guaranteed to produce exact output.

For more complex operations, the precision parameter indicates a minimum working precision (algorithms might allocate extra internal precision to attempt to produce an output accurate to the requested number of bits, especially when the required precision can be estimated easily, but this is not generally required).

If the precision is increased and the inputs either are exact or are computed with increased accuracy as well, the output should converge proportionally, absent any bugs. The general intended strategy for using ball arithmetic is to add a few guard bits, and then repeat the calculation as necessary with an exponentially increasing number of guard bits (Ziv's strategy) until the result is exact enough for one's purposes (typically the first attempt will be successful).

The following balls with an infinite or NaN component are permitted, and may be returned as output from functions.

- The ball  $[+\infty \pm c]$ , where  $c$  is finite, represents the point at positive infinity. Such a ball can always be replaced by  $[+\infty \pm 0]$  while preserving mathematical correctness (this is currently not done automatically by the library).
- The ball  $[-\infty \pm c]$ , where  $c$  is finite, represents the point at negative infinity. Such a ball can always be replaced by  $[-\infty \pm 0]$  while preserving mathematical correctness (this is currently not done automatically by the library).
- The ball  $[c \pm \infty]$ , where  $c$  is finite or infinite, represents the whole extended real line  $[-\infty, +\infty]$ . Such a ball can always be replaced by  $[0 \pm \infty]$  while preserving mathematical correctness (this is currently not done automatically by the library). Note that there is no way to represent a half-infinite interval such as  $[0, \infty]$ .
- The ball  $[\text{NaN} \pm c]$ , where  $c$  is finite or infinite, represents an indeterminate value (the value could be any extended real number, or it could represent a function being evaluated outside its domain).

of definition, for example where the result would be complex). Such an indeterminate ball can always be replaced by  $[\text{NaN} \pm \infty]$  while preserving mathematical correctness (this is currently not done automatically by the library).

### 4.1.1 Types, macros and constants

**arb\_struct**

**arb\_t**

An *arb\_struct* consists of an *arf\_struct* (the midpoint) and a *mag\_struct* (the radius). An *arb\_t* is defined as an array of length one of type *arb\_struct*, permitting an *arb\_t* to be passed by reference.

**arb\_ptr**

Alias for *arb\_struct* \*, used for vectors of numbers.

**arb\_srcptr**

Alias for *const arb\_struct* \*, used for vectors of numbers when passed as constant input to functions.

**arb\_midref(x)**

Macro returning a pointer to the midpoint of *x* as an *arf\_t*.

**arb\_radref(x)**

Macro returning a pointer to the radius of *x* as a *mag\_t*.

### 4.1.2 Memory management

**void arb\_init(arb\_t x)**

Initializes the variable *x* for use. Its midpoint and radius are both set to zero.

**void arb\_clear(arb\_t x)**

Clears the variable *x*, freeing or recycling its allocated memory.

**arb\_ptr \_arb\_vec\_init(slong n)**

Returns a pointer to an array of *n* initialized *arb\_struct* entries.

**void \_arb\_vec\_clear(arb\_ptr v, slong n)**

Clears an array of *n* initialized *arb\_struct* entries.

**void arb\_swap(arb\_t x, arb\_t y)**

Swaps *x* and *y* efficiently.

**slong arb\_allocated\_bytes(const arb\_t x)**

Returns the total number of bytes heap-allocated internally by this object. The count excludes the size of the structure itself. Add `sizeof(arb_struct)` to get the size of the object as a whole.

**slong \_arb\_vec\_allocated\_bytes(arb\_srcptr vec, slong len)**

Returns the total number of bytes allocated for this vector, i.e. the space taken up by the vector itself plus the sum of the internal heap allocation sizes for all its member elements.

**double \_arb\_vec\_estimate\_allocated\_bytes(slong len, slong prec)**

Estimates the number of bytes that need to be allocated for a vector of *len* elements with *prec* bits of precision, including the space for internal limb data. This function returns a *double* to avoid overflow issues when both *len* and *prec* are large.

This is only an approximation of the physical memory that will be used by an actual vector. In practice, the space varies with the content of the numbers; for example, zeros and small integers require no internal heap allocation even if the precision is huge. The estimate assumes that exponents will not be bignums. The actual amount may also be higher or lower due to overhead in the memory allocator or overcommitment by the operating system.

### 4.1.3 Assignment and rounding

void **arb\_set**(*arb\_t* y, const *arb\_t* x)

void **arb\_set\_arf**(*arb\_t* y, const *arf\_t* x)

void **arb\_set\_si**(*arb\_t* y, *slong* x)

void **arb\_set\_ui**(*arb\_t* y, *ulong* x)

void **arb\_set\_d**(*arb\_t* y, double x)

void **arb\_set\_fmpz**(*arb\_t* y, const *fmpz\_t* x)  
Sets *y* to the value of *x* without rounding.

void **arb\_set\_fmpz\_2exp**(*arb\_t* y, const *fmpz\_t* x, const *fmpz\_t* e)  
Sets *y* to  $x \cdot 2^e$ .

void **arb\_set\_round**(*arb\_t* y, const *arb\_t* x, *slong* prec)

void **arb\_set\_round\_fmpz**(*arb\_t* y, const *fmpz\_t* x, *slong* prec)  
Sets *y* to the value of *x*, rounded to *prec* bits.

void **arb\_set\_round\_fmpz\_2exp**(*arb\_t* y, const *fmpz\_t* x, const *fmpz\_t* e, *slong* prec)  
Sets *y* to  $x \cdot 2^e$ , rounded to *prec* bits.

void **arb\_set\_fmpq**(*arb\_t* y, const *fmpq\_t* x, *slong* prec)  
Sets *y* to the rational number *x*, rounded to *prec* bits.

int **arb\_set\_str**(*arb\_t* res, const char \* *inp*, *slong* prec)

Sets *res* to the value specified by the human-readable string *inp*. The input may be a decimal floating-point literal, such as “25”, “0.001”, “7e+141” or “-31.4159e-1”, and may also consist of two such literals separated by the symbol “+/-” and optionally enclosed in brackets, e.g. “[3.25 +/- 0.0001]”, or simply “[+/- 10]” with an implicit zero midpoint. The output is rounded to *prec* bits, and if the binary-to-decimal conversion is inexact, the resulting error is added to the radius.

The symbols “inf” and “nan” are recognized (a nan midpoint results in an indeterminate interval, with infinite radius).

Returns 0 if successful and nonzero if unsuccessful. If unsuccessful, the result is set to an indeterminate interval.

char \* **arb\_get\_str**(const *arb\_t* x, *slong* n, *ulong* flags)

Returns a nice human-readable representation of *x*, with at most *n* digits of the midpoint printed.

With default flags, the output can be parsed back with **arb\_set\_str()**, and this is guaranteed to produce an interval containing the original interval *x*.

By default, the output is rounded so that the value given for the midpoint is correct up to 1 ulp (unit in the last decimal place).

If **ARB\_STR\_MORE** is added to *flags*, more (possibly incorrect) digits may be printed.

If **ARB\_STR\_NO\_RADIUS** is added to *flags*, the radius is not included in the output if at least 1 digit of the midpoint can be printed.

By adding a multiple *m* of **ARB\_STR\_CONDENSE** to *flags*, strings of more than three times *m* consecutive digits are condensed, only printing the leading and trailing *m* digits along with brackets indicating the number of digits omitted (useful when computing values to extremely high precision).

### 4.1.4 Assignment of special values

void **arb\_zero**(*arb\_t* x)  
Sets *x* to zero.

void **arb\_one**(*arb\_t* *f*)  
Sets  $x$  to the exact integer 1.

void **arb\_pos\_inf**(*arb\_t* *x*)  
Sets  $x$  to positive infinity, with a zero radius.

void **arb\_neg\_inf**(*arb\_t* *x*)  
Sets  $x$  to negative infinity, with a zero radius.

void **arb\_zero\_pm\_inf**(*arb\_t* *x*)  
Sets  $x$  to  $[0 \pm \infty]$ , representing the whole extended real line.

void **arb\_indeterminate**(*arb\_t* *x*)  
Sets  $x$  to  $[\text{NaN} \pm \infty]$ , representing an indeterminate result.

### 4.1.5 Input and output

The *arb\_print...* functions print to standard output, while *arb\_fprint...* functions print to the stream *file*.

void **arb\_print**(const *arb\_t* *x*)

void **arb\_fprint**(FILE \* *file*, const *arb\_t* *x*)  
Prints the internal representation of  $x$ .

void **arb\_printd**(const *arb\_t* *x*, *slong* *digits*)

void **arb\_fprintd**(FILE \* *file*, const *arb\_t* *x*, *slong* *digits*)  
Prints  $x$  in decimal. The printed value of the radius is not adjusted to compensate for the fact that the binary-to-decimal conversion of both the midpoint and the radius introduces additional error.

void **arb\_printn**(const *arb\_t* *x*, *slong* *digits*, *ulong* *flags*)

void **arb\_fprintn**(FILE \* *file*, const *arb\_t* *x*, *slong* *digits*, *ulong* *flags*)  
Prints a nice decimal representation of  $x$ . By default, the output shows the midpoint with a guaranteed error of at most one unit in the last decimal place. In addition, an explicit error bound is printed so that the displayed decimal interval is guaranteed to enclose  $x$ . See *arb\_get\_str()* for details.

### 4.1.6 Random number generation

void **arb\_randtest**(*arb\_t* *x*, flint\_rand\_t *state*, *slong* *prec*, *slong* *mag\_bits*)  
Generates a random ball. The midpoint and radius will both be finite.

void **arb\_randtest\_exact**(*arb\_t* *x*, flint\_rand\_t *state*, *slong* *prec*, *slong* *mag\_bits*)  
Generates a random number with zero radius.

void **arb\_randtest\_precise**(*arb\_t* *x*, flint\_rand\_t *state*, *slong* *prec*, *slong* *mag\_bits*)  
Generates a random number with radius around  $2^{-\text{prec}}$  the magnitude of the midpoint.

void **arb\_randtest\_wide**(*arb\_t* *x*, flint\_rand\_t *state*, *slong* *prec*, *slong* *mag\_bits*)  
Generates a random number with midpoint and radius chosen independently, possibly giving a very large interval.

void **arb\_randtest\_special**(*arb\_t* *x*, flint\_rand\_t *state*, *slong* *prec*, *slong* *mag\_bits*)  
Generates a random interval, possibly having NaN or an infinity as the midpoint and possibly having an infinite radius.

void **arb\_get\_rand\_fmpq**(fmpq\_t *q*, flint\_rand\_t *state*, const *arb\_t* *x*, *slong* *bits*)  
Sets  $q$  to a random rational number from the interval represented by  $x$ . A denominator is chosen by multiplying the binary denominator of  $x$  by a random integer up to *bits* bits.

The outcome is undefined if the midpoint or radius of  $x$  is non-finite, or if the exponent of the midpoint or radius is so large or small that representing the endpoints as exact rational numbers would cause overflows.

### 4.1.7 Radius and interval operations

void **arb\_get\_mid\_arb**(*arb\_t*  $m$ , const *arb\_t*  $x$ )

Sets  $m$  to the midpoint of  $x$ .

void **arb\_get\_rad\_arb**(*arb\_t*  $r$ , const *arb\_t*  $x$ )

Sets  $r$  to the radius of  $x$ .

void **arb\_add\_error\_arf**(*arb\_t*  $x$ , const *arf\_t*  $err$ )

void **arb\_add\_error\_mag**(*arb\_t*  $x$ , const *mag\_t*  $err$ )

void **arb\_add\_error**(*arb\_t*  $x$ , const *arb\_t*  $err$ )

Adds the absolute value of  $err$  to the radius of  $x$  (the operation is done in-place).

void **arb\_add\_error\_2exp\_si**(*arb\_t*  $x$ , *slong*  $e$ )

void **arb\_add\_error\_2exp\_fmpz**(*arb\_t*  $x$ , const *fmpz\_t*  $e$ )

Adds  $2^e$  to the radius of  $x$ .

void **arb\_union**(*arb\_t*  $z$ , const *arb\_t*  $x$ , const *arb\_t*  $y$ , *slong*  $prec$ )

Sets  $z$  to a ball containing both  $x$  and  $y$ .

int **arb\_intersection**(*arb\_t*  $z$ , const *arb\_t*  $x$ , const *arb\_t*  $y$ , *slong*  $prec$ )

If  $x$  and  $y$  overlap according to **arb\_overlaps()**, then  $z$  is set to a ball containing the intersection of  $x$  and  $y$  and a nonzero value is returned. Otherwise zero is returned and the value of  $z$  is undefined. If  $x$  or  $y$  contains NaN, the result is NaN.

void **arb\_nonnegative\_part**(*arb\_t*  $res$ , const *arb\_t*  $x$ )

Sets  $res$  to the intersection of  $x$  with  $[0, \infty]$ . If  $x$  is nonnegative, an exact copy is made. If  $x$  is finite and contains negative numbers, an interval of the form  $[r/2 \pm r/2]$  is produced, which certainly contains no negative points. In the special case when  $x$  is strictly negative,  $res$  is set to zero.

void **arb\_get\_abs\_ubound\_arf**(*arf\_t*  $u$ , const *arb\_t*  $x$ , *slong*  $prec$ )

Sets  $u$  to the upper bound for the absolute value of  $x$ , rounded up to  $prec$  bits. If  $x$  contains NaN, the result is NaN.

void **arb\_get\_abs\_lbound\_arf**(*arf\_t*  $u$ , const *arb\_t*  $x$ , *slong*  $prec$ )

Sets  $u$  to the lower bound for the absolute value of  $x$ , rounded down to  $prec$  bits. If  $x$  contains NaN, the result is NaN.

void **arb\_get\_ubound\_arf**(*arf\_t*  $u$ , const *arb\_t*  $x$ , *long*  $prec$ )

Sets  $u$  to the upper bound for the value of  $x$ , rounded up to  $prec$  bits. If  $x$  contains NaN, the result is NaN.

void **arb\_get\_lbound\_arf**(*arf\_t*  $u$ , const *arb\_t*  $x$ , *long*  $prec$ )

Sets  $u$  to the lower bound for the value of  $x$ , rounded down to  $prec$  bits. If  $x$  contains NaN, the result is NaN.

void **arb\_get\_mag**(*mag\_t*  $z$ , const *arb\_t*  $x$ )

Sets  $z$  to an upper bound for the absolute value of  $x$ . If  $x$  contains NaN, the result is positive infinity.

void **arb\_get\_mag\_lower**(*mag\_t*  $z$ , const *arb\_t*  $x$ )

Sets  $z$  to a lower bound for the absolute value of  $x$ . If  $x$  contains NaN, the result is zero.

void **arb\_get\_mag\_lower\_nonnegative**(*mag\_t*  $z$ , const *arb\_t*  $x$ )

Sets  $z$  to a lower bound for the signed value of  $x$ , or zero if  $x$  overlaps with the negative half-axis. If  $x$  contains NaN, the result is zero.

void **arb\_get\_interval\_fmpz\_2exp**(fmpz\_t *a*, fmpz\_t *b*, fmpz\_t *exp*, const arb\_t *x*)

Computes the exact interval represented by *x*, in the form of an integer interval multiplied by a power of two, i.e.  $x = [a, b] \times 2^{\text{exp}}$ . The result is normalized by removing common trailing zeros from *a* and *b*.

This method aborts if *x* is infinite or NaN, or if the difference between the exponents of the midpoint and the radius is so large that allocating memory for the result fails.

Warning: this method will allocate a huge amount of memory to store the result if the exponent difference is huge. Memory allocation could succeed even if the required space is far larger than the physical memory available on the machine, resulting in swapping. It is recommended to check that the midpoint and radius of *x* both are within a reasonable range before calling this method.

void **arb\_set\_interval\_arf**(arb\_t *x*, const arf\_t *a*, const arf\_t *b*, slong *prec*)

void **arb\_set\_interval\_mpfr**(arb\_t *x*, const mpfr\_t *a*, const mpfr\_t *b*, slong *prec*)

Sets *x* to a ball containing the interval  $[a, b]$ . We require that  $a \leq b$ .

void **arb\_get\_interval\_arf**(arf\_t *a*, arf\_t *b*, const arb\_t *x*, slong *prec*)

void **arb\_get\_interval\_mpfr**(mpfr\_t *a*, mpfr\_t *b*, const arb\_t *x*)

Constructs an interval  $[a, b]$  containing the ball *x*. The MPFR version uses the precision of the output variables.

slong **arb\_rel\_error\_bits**(const arb\_t *x*)

Returns the effective relative error of *x* measured in bits, defined as the difference between the position of the top bit in the radius and the top bit in the midpoint, plus one. The result is clamped between plus/minus *ARF\_PREC\_EXACT*.

slong **arb\_rel\_accuracy\_bits**(const arb\_t *x*)

Returns the effective relative accuracy of *x* measured in bits, equal to the negative of the return value from *arb\_rel\_error\_bits()*.

slong **arb\_bits**(const arb\_t *x*)

Returns the number of bits needed to represent the absolute value of the mantissa of the midpoint of *x*, i.e. the minimum precision sufficient to represent *x* exactly. Returns 0 if the midpoint of *x* is a special value.

void **arb\_trim**(arb\_t *y*, const arb\_t *x*)

Sets *y* to a trimmed copy of *x*: rounds *x* to a number of bits equal to the accuracy of *x* (as indicated by its radius), plus a few guard bits. The resulting ball is guaranteed to contain *x*, but is more economical if *x* has less than full accuracy.

int **arb\_get\_unique\_fmpz**(fmpz\_t *z*, const arb\_t *x*)

If *x* contains a unique integer, sets *z* to that value and returns nonzero. Otherwise (if *x* represents no integers or more than one integer), returns zero.

This method aborts if there is a unique integer but that integer is so large that allocating memory for the result fails.

Warning: this method will allocate a huge amount of memory to store the result if there is a unique integer and that integer is huge. Memory allocation could succeed even if the required space is far larger than the physical memory available on the machine, resulting in swapping. It is recommended to check that the midpoint of *x* is within a reasonable range before calling this method.

void **arb\_floor**(arb\_t *y*, const arb\_t *x*, slong *prec*)

void **arb\_ceil**(arb\_t *y*, const arb\_t *x*, slong *prec*)

Sets *y* to a ball containing  $\lfloor x \rfloor$  and  $\lceil x \rceil$  respectively, with the midpoint of *y* rounded to at most *prec* bits.

void **arb\_get\_fmpz\_mid\_rad\_10exp**(fmpz\_t *mid*, fmpz\_t *rad*, fmpz\_t *exp*, const arb\_t *x*, slong *n*)

Assuming that *x* is finite and not exactly zero, computes integers *mid*, *rad*, *exp* such that  $x \in [m - r, m + r] \times 10^e$  and such that the larger out of *mid* and *rad* has at least *n* digits plus a few guard digits. If *x* is infinite or exactly zero, the outputs are all set to zero.

int **arb\_can\_round\_arf**(const *arb\_t* *x*, *slong* *prec*, *arf\_rnd\_t* *rnd*)

int **arb\_can\_round\_mpfr**(const *arb\_t* *x*, *slong* *prec*, *mpfr\_rnd\_t* *rnd*)

Returns nonzero if rounding the midpoint of *x* to *prec* bits in the direction *rnd* is guaranteed to give the unique correctly rounded floating-point approximation for the real number represented by *x*.

In other words, if this function returns nonzero, applying *arf\_set\_round()*, or *arf\_get\_mpfr()*, or *arf\_get\_d()* to the midpoint of *x* is guaranteed to return a correctly rounded *arf\_t*, *mpfr\_t* (provided that *prec* is the precision of the output variable), or *double* (provided that *prec* is 53). Moreover, *arf\_get\_mpfr()* is guaranteed to return the correct ternary value according to MPFR semantics.

Note that the *mpfr* version of this function takes an MPFR rounding mode symbol as input, while the *arf* version takes an *arf* rounding mode symbol. Otherwise, the functions are identical.

This function may perform a fast, inexact test; that is, it may return zero in some cases even when correct rounding actually is possible.

To be conservative, zero is returned when *x* is non-finite, even if it is an “exact” infinity.

## 4.1.8 Comparisons

int **arb\_is\_zero**(const *arb\_t* *x*)

Returns nonzero iff the midpoint and radius of *x* are both zero.

int **arb\_is\_nonzero**(const *arb\_t* *x*)

Returns nonzero iff zero is not contained in the interval represented by *x*.

int **arb\_is\_one**(const *arb\_t* *f*)

Returns nonzero iff *x* is exactly 1.

int **arb\_is\_finite**(const *arb\_t* *x*)

Returns nonzero iff the midpoint and radius of *x* are both finite floating-point numbers, i.e. not infinities or NaN.

int **arb\_is\_exact**(const *arb\_t* *x*)

Returns nonzero iff the radius of *x* is zero.

int **arb\_is\_int**(const *arb\_t* *x*)

Returns nonzero iff *x* is an exact integer.

int **arb\_is\_int\_2exp\_si**(const *arb\_t* *x*, *slong* *e*)

Returns nonzero iff *x* exactly equals  $n2^e$  for some integer *n*.

int **arb\_equal**(const *arb\_t* *x*, const *arb\_t* *y*)

Returns nonzero iff *x* and *y* are equal as balls, i.e. have both the same midpoint and radius.

Note that this is not the same thing as testing whether both *x* and *y* certainly represent the same real number, unless either *x* or *y* is exact (and neither contains NaN). To test whether both operands *might* represent the same mathematical quantity, use *arb\_overlaps()* or *arb\_contains()*, depending on the circumstance.

int **arb\_equal\_si**(const *arb\_t* *x*, *slong* *y*)

Returns nonzero iff *x* is equal to the integer *y*.

int **arb\_is\_positive**(const *arb\_t* *x*)

int **arb\_is\_nonnegative**(const *arb\_t* *x*)

int **arb\_is\_negative**(const *arb\_t* *x*)

int **arb\_is\_nonpositive**(const *arb\_t* *x*)

Returns nonzero iff all points *p* in the interval represented by *x* satisfy, respectively,  $p > 0$ ,  $p \geq 0$ ,  $p < 0$ ,  $p \leq 0$ . If *x* contains NaN, returns zero.

int **arb\_overlaps**(const *arb\_t* x, const *arb\_t* y)

Returns nonzero iff  $x$  and  $y$  have some point in common. If either  $x$  or  $y$  contains NaN, this function always returns nonzero (as a NaN could be anything, it could in particular contain any number that is included in the other operand).

int **arb\_contains\_arf**(const *arb\_t* x, const *arf\_t* y)

int **arb\_contains\_fmpq**(const *arb\_t* x, const *fmpq\_t* y)

int **arb\_contains\_fmpz**(const *arb\_t* x, const *fmpz\_t* y)

int **arb\_contains\_si**(const *arb\_t* x, *slong* y)

int **arb\_contains\_mpfr**(const *arb\_t* x, const *mpfr\_t* y)

int **arb\_contains**(const *arb\_t* x, const *arb\_t* y)

Returns nonzero iff the given number (or ball)  $y$  is contained in the interval represented by  $x$ .

If  $x$  contains NaN, this function always returns nonzero (as it could represent anything, and in particular could represent all the points included in  $y$ ). If  $y$  contains NaN and  $x$  does not, it always returns zero.

int **arb\_contains\_int**(const *arb\_t* x)

Returns nonzero iff the interval represented by  $x$  contains an integer.

int **arb\_contains\_zero**(const *arb\_t* x)

int **arb\_contains\_negative**(const *arb\_t* x)

int **arb\_contains\_nonpositive**(const *arb\_t* x)

int **arb\_contains\_positive**(const *arb\_t* x)

int **arb\_contains\_nonnegative**(const *arb\_t* x)

Returns nonzero iff there is any point  $p$  in the interval represented by  $x$  satisfying, respectively,  $p = 0$ ,  $p < 0$ ,  $p \leq 0$ ,  $p > 0$ ,  $p \geq 0$ . If  $x$  contains NaN, returns nonzero.

int **arb\_eq**(const *arb\_t* x, const *arb\_t* y)

int **arb\_ne**(const *arb\_t* x, const *arb\_t* y)

int **arb\_lt**(const *arb\_t* x, const *arb\_t* y)

int **arb\_le**(const *arb\_t* x, const *arb\_t* y)

int **arb\_gt**(const *arb\_t* x, const *arb\_t* y)

int **arb\_ge**(const *arb\_t* x, const *arb\_t* y)

Respectively performs the comparison  $x = y$ ,  $x \neq y$ ,  $x < y$ ,  $x \leq y$ ,  $x > y$ ,  $x \geq y$  in a mathematically meaningful way. If the comparison  $t(\text{op})u$  holds for all  $t \in x$  and all  $u \in y$ , returns 1. Otherwise, returns 0.

The balls  $x$  and  $y$  are viewed as subintervals of the extended real line. Note that balls that are formally different can compare as equal under this definition: for example,  $[-\infty \pm 3] = [-\infty \pm 0]$ . Also  $[-\infty] \leq [\infty \pm \infty]$ .

The output is always 0 if either input has NaN as midpoint.

#### 4.1.9 Arithmetic

void **arb\_neg**(*arb\_t* y, const *arb\_t* x)

void **arb\_neg\_round**(*arb\_t* y, const *arb\_t* x, *slong* prec)

Sets  $y$  to the negation of  $x$ .

void **arb\_abs**(*arb\_t* y, const *arb\_t* x)

Sets  $y$  to the absolute value of  $x$ . No attempt is made to improve the interval represented by  $x$  if it contains zero.

---

```

void arb_sgn(arb_t y, const arb_t x)
    Sets  $y$  to the sign function of  $x$ . The result is  $[0 \pm 1]$  if  $x$  contains both zero and nonzero numbers.

void arb_min(arb_t z, const arb_t x, const arb_t y, slong prec)

void arb_max(arb_t z, const arb_t x, const arb_t y, slong prec)
    Sets  $z$  respectively to the minimum and the maximum of  $x$  and  $y$ .

void arb_add(arb_t z, const arb_t x, const arb_t y, slong prec)

void arb_add_arf(arb_t z, const arb_t x, const arf_t y, slong prec)

void arb_add_ui(arb_t z, const arb_t x, ulong y, slong prec)

void arb_add_si(arb_t z, const arb_t x, slong y, slong prec)

void arb_add_fmpz(arb_t z, const arb_t x, const fmpz_t y, slong prec)
    Sets  $z = x + y$ , rounded to  $prec$  bits. The precision can be ARF_PREC_EXACT provided that
    the result fits in memory.

void arb_add_fmpz_2exp(arb_t z, const arb_t x, const fmpz_t m, const fmpz_t e, slong prec)
    Sets  $z = x + m \cdot 2^e$ , rounded to  $prec$  bits. The precision can be ARF_PREC_EXACT provided
    that the result fits in memory.

void arb_sub(arb_t z, const arb_t x, const arb_t y, slong prec)

void arb_sub_arf(arb_t z, const arb_t x, const arf_t y, slong prec)

void arb_sub_ui(arb_t z, const arb_t x, ulong y, slong prec)

void arb_sub_si(arb_t z, const arb_t x, slong y, slong prec)

void arb_sub_fmpz(arb_t z, const arb_t x, const fmpz_t y, slong prec)
    Sets  $z = x - y$ , rounded to  $prec$  bits. The precision can be ARF_PREC_EXACT provided that
    the result fits in memory.

void arb_mul(arb_t z, const arb_t x, const arb_t y, slong prec)

void arb_mul_arf(arb_t z, const arb_t x, const arf_t y, slong prec)

void arb_mul_si(arb_t z, const arb_t x, slong y, slong prec)

void arb_mul_ui(arb_t z, const arb_t x, ulong y, slong prec)

void arb_mul_fmpz(arb_t z, const arb_t x, const fmpz_t y, slong prec)
    Sets  $z = x \cdot y$ , rounded to  $prec$  bits. The precision can be ARF_PREC_EXACT provided that
    the result fits in memory.

void arb_mul_2exp_si(arb_t y, const arb_t x, slong e)

void arb_mul_2exp_fmpz(arb_t y, const arb_t x, const fmpz_t e)
    Sets  $y$  to  $x$  multiplied by  $2^e$ .

void arb_addmul(arb_t z, const arb_t x, const arb_t y, slong prec)

void arb_addmul_arf(arb_t z, const arb_t x, const arf_t y, slong prec)

void arb_addmul_si(arb_t z, const arb_t x, slong y, slong prec)

void arb_addmul_ui(arb_t z, const arb_t x, ulong y, slong prec)

void arb_addmul_fmpz(arb_t z, const arb_t x, const fmpz_t y, slong prec)
    Sets  $z = z + x \cdot y$ , rounded to  $prec$  bits. The precision can be ARF_PREC_EXACT provided that
    the result fits in memory.

void arb_submul(arb_t z, const arb_t x, const arb_t y, slong prec)

void arb_submul_arf(arb_t z, const arb_t x, const arf_t y, slong prec)

void arb_submul_si(arb_t z, const arb_t x, slong y, slong prec)

void arb_submul_ui(arb_t z, const arb_t x, ulong y, slong prec)

```

void **arb\_submul\_fmpz**(*arb\_t* z, const *arb\_t* x, const *fmpz\_t* y, *slong* prec)  
Sets  $z = z - x \cdot y$ , rounded to *prec* bits. The precision can be *ARF\_PREC\_EXACT* provided that the result fits in memory.

void **arb\_inv**(*arb\_t* y, const *arb\_t* x, *slong* prec)  
Sets  $z$  to  $1/x$ .

void **arb\_div**(*arb\_t* z, const *arb\_t* x, const *arb\_t* y, *slong* prec)

void **arb\_div\_arf**(*arb\_t* z, const *arb\_t* x, const *arf\_t* y, *slong* prec)

void **arb\_div\_si**(*arb\_t* z, const *arb\_t* x, *slong* y, *slong* prec)

void **arb\_div\_ui**(*arb\_t* z, const *arb\_t* x, *ulong* y, *slong* prec)

void **arb\_div\_fmpz**(*arb\_t* z, const *arb\_t* x, const *fmpz\_t* y, *slong* prec)

void **arb\_fmpz\_div\_fmpz**(*arb\_t* z, const *fmpz\_t* x, const *fmpz\_t* y, *slong* prec)

void **arb\_ui\_div**(*arb\_t* z, *ulong* x, const *arb\_t* y, *slong* prec)  
Sets  $z = x/y$ , rounded to *prec* bits. If  $y$  contains zero,  $z$  is set to  $0 \pm \infty$ . Otherwise, error propagation uses the rule

$$\left| \frac{x}{y} - \frac{x + \xi_1 a}{y + \xi_2 b} \right| = \left| \frac{x\xi_2 b - y\xi_1 a}{y(y + \xi_2 b)} \right| \leq \frac{|xb| + |ya|}{|y|(|y| - b)}$$

where  $-1 \leq \xi_1, \xi_2 \leq 1$ , and where the triangle inequality has been applied to the numerator and the reverse triangle inequality has been applied to the denominator.

void **arb\_div\_2expm1\_ui**(*arb\_t* z, const *arb\_t* x, *ulong* n, *slong* prec)  
Sets  $z = x/(2^n - 1)$ , rounded to *prec* bits.

#### 4.1.10 Powers and roots

void **arb\_sqrt**(*arb\_t* z, const *arb\_t* x, *slong* prec)

void **arb\_sqrt\_arf**(*arb\_t* z, const *arf\_t* x, *slong* prec)

void **arb\_sqrt\_fmpz**(*arb\_t* z, const *fmpz\_t* x, *slong* prec)

void **arb\_sqrt\_ui**(*arb\_t* z, *ulong* x, *slong* prec)  
Sets  $z$  to the square root of  $x$ , rounded to *prec* bits.

If  $x = m \pm x$  where  $m \geq r \geq 0$ , the propagated error is bounded by  $\sqrt{m} - \sqrt{m-r} = \sqrt{m}(1 - \sqrt{1-r/m}) \leq \sqrt{m}(r/m + (r/m)^2)/2$ .

void **arb\_sqrt\_pos**(*arb\_t* z, const *arb\_t* x, *slong* prec)  
Sets  $z$  to the square root of  $x$ , assuming that  $x$  represents a nonnegative number (i.e. discarding any negative numbers in the input interval).

void **arb\_hypot**(*arb\_t* z, const *arb\_t* x, const *arb\_t* y, *slong* prec)  
Sets  $z$  to  $\sqrt{x^2 + y^2}$ .

void **arb\_rsqrt**(*arb\_t* z, const *arb\_t* x, *slong* prec)

void **arb\_rsqrt\_ui**(*arb\_t* z, *ulong* x, *slong* prec)  
Sets  $z$  to the reciprocal square root of  $x$ , rounded to *prec* bits. At high precision, this is faster than computing a square root.

void **arb\_sqrt1pm1**(*arb\_t* z, const *arb\_t* x, *slong* prec)  
Sets  $z = \sqrt{1+x} - 1$ , computed accurately when  $x \approx 0$ .

void **arb\_root\_ui**(*arb\_t* z, const *arb\_t* x, *ulong* k, *slong* prec)  
Sets  $z$  to the  $k$ -th root of  $x$ , rounded to *prec* bits. This function selects between different algorithms. For large  $k$ , it evaluates  $\exp(\log(x)/k)$ . For small  $k$ , it uses *arf\_root()* at the midpoint and

computes a propagated error bound as follows: if input interval is  $[m - r, m + r]$  with  $r \leq m$ , the error is largest at  $m - r$  where it satisfies

$$\begin{aligned} m^{1/k} - (m - r)^{1/k} &= m^{1/k} [1 - (1 - r/m)^{1/k}] \\ &= m^{1/k} [1 - \exp(\log(1 - r/m)/k)] \\ &\leq m^{1/k} \min(1, -\log(1 - r/m)/k) \\ &= m^{1/k} \min(1, \log(1 + r/(m - r))/k). \end{aligned}$$

This is evaluated using `mag_log1p()`.

void **arb\_root**(*arb\_t* z, const *arb\_t* x, *ulong* k, *slong* prec)

Alias for `arb_root_ui()`, provided for backwards compatibility.

void **arb\_sqr**(*arb\_t* y, const *arb\_t* x, *slong* prec)

Sets *y* to be the square of *x*.

void **arb\_pow\_fmpz\_binexp**(*arb\_t* y, const *arb\_t* b, const *fmpz\_t* e, *slong* prec)

void **arb\_pow\_fmpz**(*arb\_t* y, const *arb\_t* b, const *fmpz\_t* e, *slong* prec)

void **arb\_pow\_ui**(*arb\_t* y, const *arb\_t* b, *ulong* e, *slong* prec)

void **arb\_ui\_pow\_ui**(*arb\_t* y, *ulong* b, *ulong* e, *slong* prec)

void **arb\_si\_pow\_ui**(*arb\_t* y, *slong* b, *ulong* e, *slong* prec)

Sets  $y = b^e$  using binary exponentiation (with an initial division if  $e < 0$ ). Provided that *b* and *e* are small enough and the exponent is positive, the exact power can be computed by setting the precision to `ARF_PREC_EXACT`.

Note that these functions can get slow if the exponent is extremely large (in such cases `arb_pow()` may be superior).

void **arb\_pow\_fmpq**(*arb\_t* y, const *arb\_t* x, const *fmpq\_t* a, *slong* prec)

Sets  $y = b^e$ , computed as  $y = (b^{1/q})^p$  if the denominator of  $e = p/q$  is small, and generally as  $y = \exp(e \log b)$ .

Note that this function can get slow if the exponent is extremely large (in such cases `arb_pow()` may be superior).

void **arb\_pow**(*arb\_t* z, const *arb\_t* x, const *arb\_t* y, *slong* prec)

Sets  $z = x^y$ , computed using binary exponentiation if *y* is a small exact integer, as  $z = (x^{1/2})^{2y}$  if *y* is a small exact half-integer, and generally as  $z = \exp(y \log x)$ .

#### 4.1.11 Exponentials and logarithms

void **arb\_log\_ui**(*arb\_t* z, *ulong* x, *slong* prec)

void **arb\_log\_fmpz**(*arb\_t* z, const *fmpz\_t* x, *slong* prec)

void **arb\_log\_arf**(*arb\_t* z, const *arf\_t* x, *slong* prec)

void **arb\_log**(*arb\_t* z, const *arb\_t* x, *slong* prec)

Sets  $z = \log(x)$ .

At low to medium precision (up to about 4096 bits), `arb_log_arf()` uses table-based argument reduction and fast Taylor series evaluation via `_arb_atan_taylor_rs()`. At high precision, it falls back to MPFR. The function `arb_log()` simply calls `arb_log_arf()` with the midpoint as input, and separately adds the propagated error.

void **arb\_log\_ui\_from\_prev**(*arb\_t* log\_k1, *ulong* k1, *arb\_t* log\_k0, *ulong* k0, *slong* prec)

Computes  $\log(k_1)$ , given  $\log(k_0)$  where  $k_0 < k_1$ . At high precision, this function uses the formula  $\log(k_1) = \log(k_0) + 2 \operatorname{atanh}((k_1 - k_0)/(k_1 + k_0))$ , evaluating the inverse hyperbolic tangent using binary splitting (for best efficiency,  $k_0$  should be large and  $k_1 - k_0$  should be small). Otherwise, it ignores  $\log(k_0)$  and evaluates the logarithm the usual way.

void **arb\_log1p**(*arb\_t* z, const *arb\_t* x, *slong prec*)  
Sets  $z = \log(1 + x)$ , computed accurately when  $x \approx 0$ .

void **arb\_log\_base\_ui**(*arb\_t* res, const *arb\_t* x, *ulong b*, *slong prec*)  
Sets  $res$  to  $\log_b(x)$ . The result is computed exactly when possible.

void **arb\_exp**(*arb\_t* z, const *arb\_t* x, *slong prec*)  
Sets  $z = \exp(x)$ . Error propagation is done using the following rule: assuming  $x = m \pm r$ , the error is largest at  $m + r$ , and we have  $\exp(m + r) - \exp(m) = \exp(m)(\exp(r) - 1) \leq r \exp(m + r)$ .

void **arb\_expml**(*arb\_t* z, const *arb\_t* x, *slong prec*)  
Sets  $z = \exp(x) - 1$ , computed accurately when  $x \approx 0$ .

void **arb\_exp\_invexp**(*arb\_t* z, *arb\_t* w, const *arb\_t* x, *slong prec*)  
Sets  $z = \exp(x)$  and  $w = \exp(-x)$ . The second exponential is computed from the first using a division, but propagated error bounds are computed separately.

### 4.1.12 Trigonometric functions

void **arb\_sin**(*arb\_t* s, const *arb\_t* x, *slong prec*)

void **arb\_cos**(*arb\_t* c, const *arb\_t* x, *slong prec*)

void **arb\_sin\_cos**(*arb\_t* s, *arb\_t* c, const *arb\_t* x, *slong prec*)  
Sets  $s = \sin(x)$ ,  $c = \cos(x)$ . Error propagation uses the rule  $|\sin(m \pm r) - \sin(m)| \leq \min(r, 2)$ .

void **arb\_sin\_pi**(*arb\_t* s, const *arb\_t* x, *slong prec*)

void **arb\_cos\_pi**(*arb\_t* c, const *arb\_t* x, *slong prec*)

void **arb\_sin\_cos\_pi**(*arb\_t* s, *arb\_t* c, const *arb\_t* x, *slong prec*)  
Sets  $s = \sin(\pi x)$ ,  $c = \cos(\pi x)$ .

void **arb\_tan**(*arb\_t* y, const *arb\_t* x, *slong prec*)  
Sets  $y = \tan(x) = \sin(x) / \cos(x)$ .

void **arb\_cot**(*arb\_t* y, const *arb\_t* x, *slong prec*)  
Sets  $y = \cot(x) = \cos(x) / \sin(x)$ .

void **arb\_sin\_cos\_pi\_fmpq**(*arb\_t* s, *arb\_t* c, const *fmpq\_t* x, *slong prec*)

void **arb\_sin\_pi\_fmpq**(*arb\_t* s, const *fmpq\_t* x, *slong prec*)

void **arb\_cos\_pi\_fmpq**(*arb\_t* c, const *fmpq\_t* x, *slong prec*)  
Sets  $s = \sin(\pi x)$ ,  $c = \cos(\pi x)$  where  $x$  is a rational number (whose numerator and denominator are assumed to be reduced). We first use trigonometric symmetries to reduce the argument to the octant  $[0, 1/4]$ . Then we either multiply by a numerical approximation of  $\pi$  and evaluate the trigonometric function the usual way, or we use algebraic methods, depending on which is estimated to be faster. Since the argument has been reduced to the first octant, the first of these two methods gives full accuracy even if the original argument is close to some root other than the origin.

void **arb\_tan\_pi**(*arb\_t* y, const *arb\_t* x, *slong prec*)  
Sets  $y = \tan(\pi x)$ .

void **arb\_cot\_pi**(*arb\_t* y, const *arb\_t* x, *slong prec*)  
Sets  $y = \cot(\pi x)$ .

void **arb\_sinc**(*arb\_t* z, const *arb\_t* x, *slong prec*)  
Sets  $z = \text{sinc}(x) = \sin(x) / x$ .

void **arb\_sinc\_pi**(*arb\_t* z, const *arb\_t* x, *slong prec*)  
Sets  $z = \text{sinc}(\pi x) = \sin(\pi x) / (\pi x)$ .

### 4.1.13 Inverse trigonometric functions

void **arb\_atan\_arf**(*arb\_t* z, const *arf\_t* x, *slong* prec)

void **arb\_atan**(*arb\_t* z, const *arb\_t* x, *slong* prec)  
Sets  $z = \operatorname{atan}(x)$ .

At low to medium precision (up to about 4096 bits), **arb\_atan\_arf**() uses table-based argument reduction and fast Taylor series evaluation via **\_arb\_atan\_taylor\_rs**(). At high precision, it falls back to MPFR. The function **arb\_atan**() simply calls **arb\_atan\_arf**() with the midpoint as input, and separately adds the propagated error.

The function **arb\_atan\_arf**() uses lookup tables if possible, and otherwise falls back to **arb\_atan\_arf\_bb**().

void **arb\_atan2**(*arb\_t* z, const *arb\_t* b, const *arb\_t* a, *slong* prec)

Sets  $r$  to an the argument (phase) of the complex number  $a + bi$ , with the branch cut discontinuity on  $(-\infty, 0]$ . We define  $\operatorname{atan2}(0, 0) = 0$ , and for  $a < 0$ ,  $\operatorname{atan2}(0, a) = \pi$ .

void **arb\_asin**(*arb\_t* z, const *arb\_t* x, *slong* prec)

Sets  $z = \operatorname{asin}(x) = \operatorname{atan}(x/\sqrt{1-x^2})$ . If  $x$  is not contained in the domain  $[-1, 1]$ , the result is an indeterminate interval.

void **arb\_acos**(*arb\_t* z, const *arb\_t* x, *slong* prec)

Sets  $z = \operatorname{acos}(x) = \pi/2 - \operatorname{asin}(x)$ . If  $x$  is not contained in the domain  $[-1, 1]$ , the result is an indeterminate interval.

### 4.1.14 Hyperbolic functions

void **arb\_sinh**(*arb\_t* s, const *arb\_t* x, *slong* prec)

void **arb\_cosh**(*arb\_t* c, const *arb\_t* x, *slong* prec)

void **arb\_sinh\_cosh**(*arb\_t* s, *arb\_t* c, const *arb\_t* x, *slong* prec)

Sets  $s = \sinh(x)$ ,  $c = \cosh(x)$ . If the midpoint of  $x$  is close to zero and the hyperbolic sine is to be computed, evaluates  $(e^{2x} \pm 1)/(2e^x)$  via **arb\_exp1**() to avoid loss of accuracy. Otherwise evaluates  $(e^x \pm e^{-x})/2$ .

void **arb\_tanh**(*arb\_t* y, const *arb\_t* x, *slong* prec)

Sets  $y = \tanh(x) = \sinh(x)/\cosh(x)$ , evaluated via **arb\_exp1**() as  $\tanh(x) = (e^{2x} - 1)/(e^{2x} + 1)$  if  $|x|$  is small, and as  $\tanh(\pm x) = 1 - 2e^{\mp 2x}/(1 + e^{\mp 2x})$  if  $|x|$  is large.

void **arb\_coth**(*arb\_t* y, const *arb\_t* x, *slong* prec)

Sets  $y = \operatorname{coth}(x) = \cosh(x)/\sinh(x)$ , evaluated using the same strategy as **arb\_tanh**() .

### 4.1.15 Inverse hyperbolic functions

void **arb\_atanh**(*arb\_t* z, const *arb\_t* x, *slong* prec)

Sets  $z = \operatorname{atanh}(x)$ .

void **arb\_asinh**(*arb\_t* z, const *arb\_t* x, *slong* prec)

Sets  $z = \operatorname{asinh}(x)$ .

void **arb\_acosh**(*arb\_t* z, const *arb\_t* x, *slong* prec)

Sets  $z = \operatorname{acosh}(x)$ . If  $x < 1$ , the result is an indeterminate interval.

### 4.1.16 Constants

The following functions cache the computed values to speed up repeated calls at the same or lower precision. For further implementation details, see *Algorithms for mathematical constants*.

void **arb\_const\_pi**(*arb\_t* z, *slong* prec)  
Computes  $\pi$ .

void **arb\_const\_sqrt\_pi**(*arb\_t* z, *slong* prec)  
Computes  $\sqrt{\pi}$ .

void **arb\_const\_log\_sqrt2pi**(*arb\_t* z, *slong* prec)  
Computes  $\log \sqrt{2\pi}$ .

void **arb\_const\_log2**(*arb\_t* z, *slong* prec)  
Computes  $\log(2)$ .

void **arb\_const\_log10**(*arb\_t* z, *slong* prec)  
Computes  $\log(10)$ .

void **arb\_const\_euler**(*arb\_t* z, *slong* prec)  
Computes Euler's constant  $\gamma = \lim_{k \rightarrow \infty} (H_k - \log k)$  where  $H_k = 1 + 1/2 + \dots + 1/k$ .

void **arb\_const\_catalan**(*arb\_t* z, *slong* prec)  
Computes Catalan's constant  $C = \sum_{n=0}^{\infty} (-1)^n / (2n+1)^2$ .

void **arb\_const\_e**(*arb\_t* z, *slong* prec)  
Computes  $e = \exp(1)$ .

void **arb\_const\_khinchin**(*arb\_t* z, *slong* prec)  
Computes Khinchin's constant  $K_0$ .

void **arb\_const\_glaisher**(*arb\_t* z, *slong* prec)  
Computes the Glaisher-Kinkelin constant  $A = \exp(1/12 - \zeta'(-1))$ .

void **arb\_const\_apery**(*arb\_t* z, *slong* prec)  
Computes Apery's constant  $\zeta(3)$ .

#### 4.1.17 Lambert W function

void **arb\_lambertw**(*arb\_t* res, const *arb\_t* x, int flags, *slong* prec)  
Computes the Lambert W function, which solves the equation  $we^w = x$ .

The Lambert W function has infinitely many complex branches  $W_k(x)$ , two of which are real on a part of the real line. The principal branch  $W_0(x)$  is selected by setting *flags* to 0, and the  $W_{-1}$  branch is selected by setting *flags* to 1. The principal branch is real-valued for  $x \geq -1/e$  (taking values in  $[-1, +\infty)$ ) and the  $W_{-1}$  branch is real-valued for  $-1/e \leq x < 0$  and takes values in  $(-\infty, -1]$ . Elsewhere, the Lambert W function is complex and **acb\_lambertw()** should be used.

The implementation first computes a floating-point approximation heuristically and then computes a rigorously certified enclosure around this approximation. Some asymptotic cases are handled specially. The algorithm used to compute the Lambert W function is described in [Joh2017b], which follows the main ideas in [CGHJK1996].

#### 4.1.18 Gamma function and factorials

void **arb\_rising\_ui\_bs**(*arb\_t* z, const *arb\_t* x, *ulong* n, *slong* prec)  
void **arb\_rising\_ui\_rs**(*arb\_t* z, const *arb\_t* x, *ulong* n, *ulong* step, *slong* prec)  
void **arb\_rising\_ui\_rec**(*arb\_t* z, const *arb\_t* x, *ulong* n, *slong* prec)  
void **arb\_rising\_ui**(*arb\_t* z, const *arb\_t* x, *ulong* n, *slong* prec)  
void **arb\_rising**(*arb\_t* z, const *arb\_t* x, const *arb\_t* n, *slong* prec)  
Computes the rising factorial  $z = x(x+1)(x+2)\cdots(x+n-1)$ .

The *bs* version uses binary splitting. The *rs* version uses rectangular splitting. The *rec* version uses either *bs* or *rs* depending on the input. The default version uses the gamma function unless *n* is a small integer.

The *rs* version takes an optional *step* parameter for tuning purposes (to use the default step length, pass zero).

```
void arb_rising_fmpq_ui(arb_t z, const fmpq_t x, ulong n, slong prec)
    Computes the rising factorial  $z = x(x+1)(x+2)\cdots(x+n-1)$  using binary splitting. If the
    denominator or numerator of  $x$  is large compared to prec, it is more efficient to convert  $x$  to an
    approximation and use arb_rising_ui().
```

```
void arb_rising2_ui_bs(arb_t u, arb_t v, const arb_t x, ulong n, slong prec)
void arb_rising2_ui_rs(arb_t u, arb_t v, const arb_t x, ulong n, ulong step, slong prec)
void arb_rising2_ui(arb_t u, arb_t v, const arb_t x, ulong n, slong prec)
    Letting  $u(x) = x(x+1)(x+2)\cdots(x+n-1)$ , simultaneously compute  $u(x)$  and  $v(x) = u'(x)$ ,
    respectively using binary splitting, rectangular splitting (with optional nonzero step length step to
    override the default choice), and an automatic algorithm choice.
```

```
void arb_fac_ui(arb_t z, ulong n, slong prec)
    Computes the factorial  $z = n!$  via the gamma function.
```

```
void arb_doublefac_ui(arb_t z, ulong n, slong prec)
    Computes the double factorial  $z = n!!$  via the gamma function.
```

```
void arb_bin_ui(arb_t z, const arb_t n, ulong k, slong prec)
void arb_bin_uiui(arb_t z, ulong n, ulong k, slong prec)
    Computes the binomial coefficient  $z = \binom{n}{k}$ , via the rising factorial as  $\binom{n}{k} = (n-k+1)_k/k!$ .
```

```
void arb_gamma(arb_t z, const arb_t x, slong prec)
void arb_gamma_fmpq(arb_t z, const fmpq_t x, slong prec)
void arb_gamma_fmpz(arb_t z, const fmpz_t x, slong prec)
    Computes the gamma function  $z = \Gamma(x)$ .
```

```
void arb_lgamma(arb_t z, const arb_t x, slong prec)
    Computes the logarithmic gamma function  $z = \log \Gamma(x)$ . The complex branch structure is assumed,
    so if  $x \leq 0$ , the result is an indeterminate interval.
```

```
void arb_rgamma(arb_t z, const arb_t x, slong prec)
    Computes the reciprocal gamma function  $z = 1/\Gamma(x)$ , avoiding division by zero at the poles of the
    gamma function.
```

```
void arb_digamma(arb_t y, const arb_t x, slong prec)
    Computes the digamma function  $z = \psi(x) = (\log \Gamma(x))' = \Gamma'(x)/\Gamma(x)$ .
```

#### 4.1.19 Zeta function

```
void arb_zeta_ui_vec_borwein(arb_ptr z, ulong start, slong num, ulong step, slong prec)
    Evaluates  $\zeta(s)$  at num consecutive integers  $s$  beginning with start and proceeding in increments of
    step. Uses Borwein's formula ([Bor2000], [GS2003]), implemented to support fast multi-evaluation
    (but also works well for a single  $s$ ).
```

Requires  $\text{start} \geq 2$ . For efficiency, the largest  $s$  should be at most about as large as *prec*. Arguments approaching *LONG\_MAX* will cause overflows. One should therefore only use this function for  $s$  up to about *prec*, and then switch to the Euler product.

The algorithm for single  $s$  is basically identical to the one used in MPFR (see [MPFR2012] for a detailed description). In particular, we evaluate the sum backwards to avoid storing more than one  $d_k$  coefficient, and use integer arithmetic throughout since it is convenient and the terms turn out to be slightly larger than  $2^{\text{prec}}$ . The only numerical error in the main loop comes from the division by  $k^s$ , which adds less than 1 unit of error per term. For fast multi-evaluation, we repeatedly divide by  $k^{\text{step}}$ . Each division reduces the input error and adds at most 1 unit of additional rounding error, so by induction, the error per term is always smaller than 2 units.

```
void arb_zeta_ui_asymp(arb_t x, ulong s, slong prec)
```

void **arb\_zeta\_ui\_euler\_product**(*arb\_t* z, *ulong* s, *slong* prec)  
Computes  $\zeta(s)$  using the Euler product. This is fast only if  $s$  is large compared to the precision. Both methods are trivial wrappers for `_acb_dirichlet_euler_product_real_ui()`.

void **arb\_zeta\_ui\_bernoulli**(*arb\_t* x, *ulong* s, *slong* prec)  
Computes  $\zeta(s)$  for even  $s$  via the corresponding Bernoulli number.

void **arb\_zeta\_ui\_borwein\_bsplitt**(*arb\_t* x, *ulong* s, *slong* prec)  
Computes  $\zeta(s)$  for arbitrary  $s \geq 2$  using a binary splitting implementation of Borwein's algorithm. This has quasilinear complexity with respect to the precision (assuming that  $s$  is fixed).

void **arb\_zeta\_ui\_vec**(*arb\_ptr* x, *ulong* start, *slong* num, *slong* prec)  
void **arb\_zeta\_ui\_vec\_even**(*arb\_ptr* x, *ulong* start, *slong* num, *slong* prec)  
void **arb\_zeta\_ui\_vec\_odd**(*arb\_ptr* x, *ulong* start, *slong* num, *slong* prec)  
Computes  $\zeta(s)$  at  $num$  consecutive integers (respectively  $num$  even or  $num$  odd integers) beginning with  $s = start \geq 2$ , automatically choosing an appropriate algorithm.

void **arb\_zeta\_ui**(*arb\_t* x, *ulong* s, *slong* prec)  
Computes  $\zeta(s)$  for nonnegative integer  $s \neq 1$ , automatically choosing an appropriate algorithm. This function is intended for numerical evaluation of isolated zeta values; for multi-evaluation, the vector versions are more efficient.

void **arb\_zeta**(*arb\_t* z, const *arb\_t* s, *slong* prec)  
Sets  $z$  to the value of the Riemann zeta function  $\zeta(s)$ .  
For computing derivatives with respect to  $s$ , use `arb_poly_zeta_series()`.

void **arb\_hurwitz\_zeta**(*arb\_t* z, const *arb\_t* s, const *arb\_t* a, *slong* prec)  
Sets  $z$  to the value of the Hurwitz zeta function  $\zeta(s, a)$ .  
For computing derivatives with respect to  $s$ , use `arb_poly_zeta_series()`.

#### 4.1.20 Bernoulli numbers and polynomials

void **arb\_bernoulli\_ui**(*arb\_t* b, *ulong* n, *slong* prec)  
void **arb\_bernoulli\_fmpz**(*arb\_t* b, const *fmpz\_t* n, *slong* prec)  
Sets  $b$  to the numerical value of the Bernoulli number  $B_n$  approximated to  $prec$  bits.  
The internal precision is increased automatically to give an accurate result. Note that, with huge *fmpz* input, the output will have a huge exponent and evaluation will accordingly be slower.  
A single division from the exact fraction of  $B_n$  is used if this value is in the global cache or the exact numerator roughly is larger than  $prec$  bits. Otherwise, the Riemann zeta function is used (see `arb_bernoulli_ui_zeta()`).  
This function reads  $B_n$  from the global cache if the number is already cached, but does not automatically extend the cache by itself.

void **arb\_bernoulli\_ui\_zeta**(*arb\_t* b, *ulong* n, *slong* prec)  
Sets  $b$  to the numerical value of  $B_n$  accurate to  $prec$  bits, computed using the formula  $B_{2n} = (-1)^{n+1} 2(2n)! \zeta(2n) / (2\pi)^n$ .  
To avoid potential infinite recursion, we explicitly call the Euler product implementation of the zeta function. This method will only give high accuracy if the precision is small enough compared to  $n$  for the Euler product to converge rapidly.

void **arb\_bernoulli\_poly\_ui**(*arb\_t* res, *ulong* n, const *arb\_t* x, *slong* prec)  
Sets  $res$  to the value of the Bernoulli polynomial  $B_n(x)$ .  
Warning: this function is only fast if either  $n$  or  $x$  is a small integer.  
This function reads Bernoulli numbers from the global cache if they are already cached, but does not automatically extend the cache by itself.

void **arb\_power\_sum\_vec**(*arb\_ptr* res, const *arb\_t* a, const *arb\_t* b, *slong* len, *slong* prec)

For  $n$  from 0 to  $len - 1$ , sets entry  $n$  in the output vector  $res$  to

$$S_n(a, b) = \frac{1}{n+1} (B_{n+1}(b) - B_{n+1}(a))$$

where  $B_n(x)$  is a Bernoulli polynomial. If  $a$  and  $b$  are integers and  $b \geq a$ , this is equivalent to

$$S_n(a, b) = \sum_{k=a}^{b-1} k^n.$$

The computation uses the generating function for Bernoulli polynomials.

#### 4.1.21 Polylogarithms

void **arb\_polylog**(*arb\_t* w, const *arb\_t* s, const *arb\_t* z, *slong* prec)

void **arb\_polylog\_si**(*arb\_t* w, *slong* s, const *arb\_t* z, *slong* prec)

Sets  $w$  to the polylogarithm  $\text{Li}_s(z)$ .

#### 4.1.22 Other special functions

void **arb\_fib\_fmpz**(*arb\_t* z, const *fmpz\_t* n, *slong* prec)

void **arb\_fib\_ui**(*arb\_t* z, *ulong* n, *slong* prec)

Computes the Fibonacci number  $F_n$ . Uses the binary squaring algorithm described in [Tak2000]. Provided that  $n$  is small enough, an exact Fibonacci number can be computed by setting the precision to  $ARF\_PREC\_EXACT$ .

void **arb\_agm**(*arb\_t* z, const *arb\_t* x, const *arb\_t* y, *slong* prec)

Sets  $z$  to the arithmetic-geometric mean of  $x$  and  $y$ .

void **arb\_chebyshev\_t\_ui**(*arb\_t* a, *ulong* n, const *arb\_t* x, *slong* prec)

void **arb\_chebyshev\_u\_ui**(*arb\_t* a, *ulong* n, const *arb\_t* x, *slong* prec)

Evaluates the Chebyshev polynomial of the first kind  $a = T_n(x)$  or the Chebyshev polynomial of the second kind  $a = U_n(x)$ .

void **arb\_chebyshev\_t2\_ui**(*arb\_t* a, *arb\_t* b, *ulong* n, const *arb\_t* x, *slong* prec)

void **arb\_chebyshev\_u2\_ui**(*arb\_t* a, *arb\_t* b, *ulong* n, const *arb\_t* x, *slong* prec)

Simultaneously evaluates  $a = T_n(x), b = T_{n-1}(x)$  or  $a = U_n(x), b = U_{n-1}(x)$ . Aliasing between  $a, b$  and  $x$  is not permitted.

void **arb\_bell\_sum\_bsplitt**(*arb\_t* res, const *fmpz\_t* n, const *fmpz\_t* a, const *fmpz\_t* b, const *fmpz\_t* mmag, *slong* prec)

void **arb\_bell\_sum\_taylor**(*arb\_t* res, const *fmpz\_t* n, const *fmpz\_t* a, const *fmpz\_t* b, const *fmpz\_t* mmag, *slong* prec)

Helper functions for Bell numbers, evaluating the sum  $\sum_{k=a}^{b-1} k^n/k!$ . If  $mmag$  is non-NULL, it may be used to indicate that the target error tolerance should be  $2^{mmag-prec}$ .

void **arb\_bell\_fmpz**(*arb\_t* res, const *fmpz\_t* n, *slong* prec)

void **arb\_bell\_ui**(*arb\_t* res, *ulong* n, *slong* prec)

Sets  $res$  to the Bell number  $B_n$ . If the number is too large to fit exactly in  $prec$  bits, a numerical approximation is computed efficiently.

The algorithm to compute Bell numbers, including error analysis, is described in detail in [Joh2015].

void **arb\_euler\_number\_fmpz**(*arb\_t* res, const *fmpz\_t* n, *slong* prec)

void **arb\_euler\_number\_ui**(*arb\_t* res, *ulong* n, *slong* prec)

Sets *res* to the Euler number  $E_n$ , which is defined by having the exponential generating function  $1/\cosh(x)$ .

The Euler product for the Dirichlet beta function (`_acb_dirichlet_euler_product_real_ui()`) is used to compute a numerical approximation. If *prec* is more than enough to represent the result exactly, the exact value is automatically determined from a lower-precision approximation.

void **arb\_partitions\_fmpz**(*arb\_t* res, const *fmpz\_t* n, *slong* prec)

void **arb\_partitions\_ui**(*arb\_t* res, *ulong* n, *slong* prec)

Sets *res* to the partition function  $p(n)$ . When *n* is large and  $\log_2 p(n)$  is more than twice *prec*, the leading term in the Hardy-Ramanujan asymptotic series is used together with an error bound. Otherwise, the exact value is computed and rounded.

### 4.1.23 Internals for computing elementary functions

void **\_arb\_atan\_taylor\_naive**(*mp\_ptr* y, *mp\_limb\_t* \* error, *mp\_srcptr* x, *mp\_size\_t* xn, *ulong* N, int alternating)

void **\_arb\_atan\_taylor\_rs**(*mp\_ptr* y, *mp\_limb\_t* \* error, *mp\_srcptr* x, *mp\_size\_t* xn, *ulong* N, int alternating)

Computes an approximation of  $y = \sum_{k=0}^{N-1} x^{2k+1}/(2k+1)$  (if *alternating* is 0) or  $y = \sum_{k=0}^{N-1} (-1)^k x^{2k+1}/(2k+1)$  (if *alternating* is 1). Used internally for computing arctangents and logarithms. The *naive* version uses the forward recurrence, and the *rs* version uses a division-avoiding rectangular splitting scheme.

Requires  $N \leq 255$ ,  $0 \leq x \leq 1/16$ , and *xn* positive. The input *x* and output *y* are fixed-point numbers with *xn* fractional limbs. A bound for the ulp error is written to *error*.

void **\_arb\_exp\_taylor\_naive**(*mp\_ptr* y, *mp\_limb\_t* \* error, *mp\_srcptr* x, *mp\_size\_t* xn, *ulong* N)

void **\_arb\_exp\_taylor\_rs**(*mp\_ptr* y, *mp\_limb\_t* \* error, *mp\_srcptr* x, *mp\_size\_t* xn, *ulong* N)

Computes an approximation of  $y = \sum_{k=0}^{N-1} x^k/k!$ . Used internally for computing exponentials. The *naive* version uses the forward recurrence, and the *rs* version uses a division-avoiding rectangular splitting scheme.

Requires  $N \leq 287$ ,  $0 \leq x \leq 1/16$ , and *xn* positive. The input *x* is a fixed-point number with *xn* fractional limbs, and the output *y* is a fixed-point number with *xn* fractional limbs plus one extra limb for the integer part of the result.

A bound for the ulp error is written to *error*.

void **\_arb\_sin\_cos\_taylor\_naive**(*mp\_ptr* ysin, *mp\_ptr* ycos, *mp\_limb\_t* \* error, *mp\_srcptr* x, *mp\_size\_t* xn, *ulong* N)

void **\_arb\_sin\_cos\_taylor\_rs**(*mp\_ptr* ysin, *mp\_ptr* ycos, *mp\_limb\_t* \* error, *mp\_srcptr* x, *mp\_size\_t* xn, *ulong* N, int *sinonly*, int *alternating*)

Computes approximations of  $y_s = \sum_{k=0}^{N-1} (-1)^k x^{2k+1}/(2k+1)!$  and  $y_c = \sum_{k=0}^{N-1} (-1)^k x^{2k}/(2k)!$ . Used internally for computing sines and cosines. The *naive* version uses the forward recurrence, and the *rs* version uses a division-avoiding rectangular splitting scheme.

Requires  $N \leq 143$ ,  $0 \leq x \leq 1/16$ , and *xn* positive. The input *x* and outputs *ysin*, *ycos* are fixed-point numbers with *xn* fractional limbs. A bound for the ulp error is written to *error*.

If *sinonly* is 1, only the sine is computed; if *sinonly* is 0 both the sine and cosine are computed. To compute sin and cos, *alternating* should be 1. If *alternating* is 0, the hyperbolic sine is computed (this is currently only intended to be used together with *sinonly*).

int **\_arb\_get\_mpn\_fixed\_mod\_log2**(*mp\_ptr* w, *fmpz\_t* q, *mp\_limb\_t* \* error, const *arf\_t* x, *mp\_size\_t* wn)

Attempts to write  $w = x - q \log(2)$  with  $0 \leq w < \log(2)$ , where *w* is a fixed-point number with *wn* limbs and ulp error *error*. Returns success.

int **\_arb\_get\_mpn\_fixed\_mod\_pi4**(*mp\_ptr* *w*, *fmpz\_t* *q*, int \* *octant*, *mp\_limb\_t* \* *error*, const *arf\_t* *x*, *mp\_size\_t* *wn*)

Attempts to write  $w = |x| - q\pi/4$  with  $0 \leq w < \pi/4$ , where  $w$  is a fixed-point number with  $wn$  limbs and ulp error *error*. Returns success.

The value of  $q \bmod 8$  is written to *octant*. The output variable *q* can be NULL, in which case the full value of  $q$  is not stored.

*slong* **\_arb\_exp\_taylor\_bound**(*slong* *mag*, *slong* *prec*)

Returns  $n$  such that  $|\sum_{k=n}^{\infty} x^k/k!| \leq 2^{-\text{prec}}$ , assuming  $|x| \leq 2^{\text{mag}} \leq 1/4$ .

void **arb\_exp\_arf\_bb**(*arb\_t* *z*, const *arf\_t* *x*, *slong* *prec*, int *m1*)

Computes the exponential function using the bit-burst algorithm. If *m1* is nonzero, the exponential function minus one is computed accurately.

Aborts if  $x$  is extremely small or large (where another algorithm should be used).

For large  $x$ , repeated halving is used. In fact, we always do argument reduction until  $|x|$  is smaller than about  $2^{-d}$  where  $d \approx 16$  to speed up convergence. If  $|x| \approx 2^m$ , we thus need about  $m + d$  squarings.

Computing  $\log(2)$  costs roughly 100-200 multiplications, so is not usually worth the effort at very high precision. However, this function could be improved by using  $\log(2)$  based reduction at precision low enough that the value can be assumed to be cached.

void **\_arb\_exp\_sum\_bs\_simple**(*fmpz\_t* *T*, *fmpz\_t* *Q*, *mp\_bitcnt\_t* \* *Qexp*, const *fmpz\_t* *x*, *mp\_bitcnt\_t* *r*, *slong* *N*)

void **\_arb\_exp\_sum\_bs\_powtab**(*fmpz\_t* *T*, *fmpz\_t* *Q*, *mp\_bitcnt\_t* \* *Qexp*, const *fmpz\_t* *x*, *mp\_bitcnt\_t* *r*, *slong* *N*)

Computes  $T$ ,  $Q$  and  $Qexp$  such that  $T/(Q2^{Qexp}) = \sum_{k=1}^N (x/2^r)^k/k!$  using binary splitting. Note that the sum is taken to  $N$  inclusive and omits the constant term.

The *powtab* version precomputes a table of powers of  $x$ , resulting in slightly higher memory usage but better speed. For best efficiency,  $N$  should have many trailing zero bits.

void **\_arb\_atan\_sum\_bs\_simple**(*fmpz\_t* *T*, *fmpz\_t* *Q*, *mp\_bitcnt\_t* \* *Qexp*, const *fmpz\_t* *x*, *mp\_bitcnt\_t* *r*, *slong* *N*)

void **\_arb\_atan\_sum\_bs\_powtab**(*fmpz\_t* *T*, *fmpz\_t* *Q*, *mp\_bitcnt\_t* \* *Qexp*, const *fmpz\_t* *x*, *mp\_bitcnt\_t* *r*, *slong* *N*)

Computes  $T$ ,  $Q$  and  $Qexp$  such that  $T/(Q2^{Qexp}) = \sum_{k=1}^N (-1)^k (x/2^r)^{2k}/(2k+1)$  using binary splitting. Note that the sum is taken to  $N$  inclusive, omits the linear term, and requires a final multiplication by  $(x/2^r)$  to give the true series for atan.

The *powtab* version precomputes a table of powers of  $x$ , resulting in slightly higher memory usage but better speed. For best efficiency,  $N$  should have many trailing zero bits.

void **arb\_atan\_arf\_bb**(*arb\_t* *z*, const *arf\_t* *x*, *slong* *prec*)

Computes the arctangent of  $x$ . Initially, the argument-halving formula

$$\text{atan}(x) = 2 \text{atan}\left(\frac{x}{1 + \sqrt{1 + x^2}}\right)$$

is applied up to 8 times to get a small argument. Then a version of the bit-burst algorithm is used. The functional equation

$$\text{atan}(x) = \text{atan}(p/q) + \text{atan}(w), \quad w = \frac{qx - p}{px + q}, \quad p = \lfloor qx \rfloor$$

is applied repeatedly instead of integrating a differential equation for the arctangent, as this appears to be more efficient.

#### 4.1.24 Vector functions

void **\_arb\_vec\_zero**(*arb\_ptr* *vec*, *slong* *n*)

Sets all entries in *vec* to zero.

`int _arb_vec_is_zero(arb_srcptr vec, slong len)`  
Returns nonzero iff all entries in *x* are zero.

`int _arb_vec_is_finite(arb_srcptr x, slong len)`  
Returns nonzero iff all entries in *x* certainly are finite.

`void _arb_vec_set(arb_ptr res, arb_srcptr vec, slong len)`  
Sets *res* to a copy of *vec*.

`void _arb_vec_set_round(arb_ptr res, arb_srcptr vec, slong len, slong prec)`  
Sets *res* to a copy of *vec*, rounding each entry to *prec* bits.

`void _arb_vec_swap(arb_ptr vec1, arb_ptr vec2, slong len)`  
Swaps the entries of *vec1* and *vec2*.

`void _arb_vec_neg(arb_ptr B, arb_srcptr A, slong n)`

`void _arb_vec_sub(arb_ptr C, arb_srcptr A, arb_srcptr B, slong n, slong prec)`

`void _arb_vec_add(arb_ptr C, arb_srcptr A, arb_srcptr B, slong n, slong prec)`

`void _arb_vec_scalar_mul(arb_ptr res, arb_srcptr vec, slong len, const arb_t c, slong prec)`

`void _arb_vec_scalar_div(arb_ptr res, arb_srcptr vec, slong len, const arb_t c, slong prec)`

`void _arb_vec_scalar_mul_fmpz(arb_ptr res, arb_srcptr vec, slong len, const fmpz_t c, slong prec)`

`void _arb_vec_scalar_mul_2exp_si(arb_ptr res, arb_srcptr src, slong len, slong c)`

`void _arb_vec_scalar_addmul(arb_ptr res, arb_srcptr vec, slong len, const arb_t c, slong prec)`  
Performs the respective scalar operation elementwise.

`void _arb_vec_dot(arb_t res, arb_srcptr vec1, arb_srcptr vec2, slong len2, slong prec)`  
Sets *res* to the dot product of *vec1* and *vec2*.

`void _arb_vec_get_mag(mag_t bound, arb_srcptr vec, slong len, slong prec)`  
Sets *bound* to an upper bound for the entries in *vec*.

*slong* `_arb_vec_bits(arb_srcptr x, slong len)`  
Returns the maximum of `arb_bits()` for all entries in *vec*.

`void _arb_vec_set_powers(arb_ptr xs, const arb_t x, slong len, slong prec)`  
Sets *xs* to the powers  $1, x, x^2, \dots, x^{len-1}$ .

`void _arb_vec_add_error_arf_vec(arb_ptr res, arf_srcptr err, slong len)`

`void _arb_vec_add_error_mag_vec(arb_ptr res, mag_srcptr err, slong len)`  
Adds the magnitude of each entry in *err* to the radius of the corresponding entry in *res*.

`void _arb_vec_indeterminate(arb_ptr vec, slong len)`  
Applies `arb_indeterminate()` elementwise.

`void _arb_vec_trim(arb_ptr res, arb_srcptr vec, slong len)`  
Applies `arb_trim()` elementwise.

`int _arb_vec_get_unique_fmpz_vec(fmpz * res, arb_srcptr vec, slong len)`  
Calls `arb_get_unique_fmpz()` elementwise and returns nonzero if all entries can be rounded uniquely to integers. If any entry in *vec* cannot be rounded uniquely to an integer, returns zero.

## 4.2 acb.h – complex numbers

An *acb\_t* represents a complex number with error bounds. An *acb\_t* consists of a pair of real number balls of type *arb\_struct*, representing the real and imaginary part with separate error bounds.

An *acb\_t* thus represents a rectangle  $[m_1 - r_1, m_1 + r_1] + [m_2 - r_2, m_2 + r_2]i$  in the complex plane. This is used instead of a disk or square representation (consisting of a complex floating-point midpoint with a single radius), since it allows implementing many operations more conveniently by splitting into ball

operations on the real and imaginary parts. It also allows tracking when complex numbers have an exact (for example exactly zero) real part and an inexact imaginary part, or vice versa.

The interface for the `acb_t` type is slightly less developed than that for the `arb_t` type. In many cases, the user can easily perform missing operations by directly manipulating the real and imaginary parts.

### 4.2.1 Types, macros and constants

**acb\_struct**

**acb\_t**

An `acb_struct` consists of a pair of `arb_struct`s. An `acb_t` is defined as an array of length one of type `acb_struct`, permitting an `acb_t` to be passed by reference.

**acb\_ptr**

Alias for `acb_struct *`, used for vectors of numbers.

**acb\_srcptr**

Alias for `const acb_struct *`, used for vectors of numbers when passed as constant input to functions.

**acb\_realref(x)**

Macro returning a pointer to the real part of  $x$  as an `arb_t`.

**acb\_imagref(x)**

Macro returning a pointer to the imaginary part of  $x$  as an `arb_t`.

### 4.2.2 Memory management

void **acb\_init**(`acb_t x`)

Initializes the variable  $x$  for use, and sets its value to zero.

void **acb\_clear**(`acb_t x`)

Clears the variable  $x$ , freeing or recycling its allocated memory.

`acb_ptr` **\_acb\_vec\_init**(`slong n`)

Returns a pointer to an array of  $n$  initialized `acb_struct`s.

void **\_acb\_vec\_clear**(`acb_ptr v`, `slong n`)

Clears an array of  $n$  initialized `acb_struct`s.

`slong` **acb\_allocated\_bytes**(`const acb_t x`)

Returns the total number of bytes heap-allocated internally by this object. The count excludes the size of the structure itself. Add `sizeof(acb_struct)` to get the size of the object as a whole.

`slong` **\_acb\_vec\_allocated\_bytes**(`acb_srcptr vec`, `slong len`)

Returns the total number of bytes allocated for this vector, i.e. the space taken up by the vector itself plus the sum of the internal heap allocation sizes for all its member elements.

double **\_acb\_vec\_estimate\_allocated\_bytes**(`slong len`, `slong prec`)

Estimates the number of bytes that need to be allocated for a vector of  $len$  elements with  $prec$  bits of precision, including the space for internal limb data. See comments for `_arb_vec_estimate_allocated_bytes()`.

### 4.2.3 Basic manipulation

void **acb\_zero**(`acb_t z`)

void **acb\_one**(`acb_t z`)

void **acb\_onei**(`acb_t z`)

Sets  $z$  respectively to 0, 1,  $i = \sqrt{-1}$ .

```
void acb_set(acb_t z, const acb_t x)
void acb_set_ui(acb_t z, slong x)
void acb_set_si(acb_t z, slong x)
void acb_set_d(acb_t z, double x)
void acb_set_fmpz(acb_t z, const fmpz_t x)
void acb_set_arb(acb_t z, const arb_t c)
    Sets z to the value of x.
void acb_set_si_si(acb_t z, slong x, slong y)
void acb_set_d_d(acb_t z, double x, double y)
void acb_set_fmpz_fmpz(acb_t z, const fmpz_t x, const fmpz_t y)
void acb_set_arb_arb(acb_t z, const arb_t x, const arb_t y)
    Sets the real and imaginary part of z to the values x and y respectively
void acb_set_fmpq(acb_t z, const fmpq_t x, slong prec)
void acb_set_round(acb_t z, const acb_t x, slong prec)
void acb_set_round_fmpz(acb_t z, const fmpz_t x, slong prec)
void acb_set_round_arb(acb_t z, const arb_t x, slong prec)
    Sets z to x, rounded to prec bits.
void acb_swap(acb_t z, acb_t x)
    Swaps z and x efficiently.
void acb_add_error_mag(acb_t x, const mag_t err)
    Adds err to the error bounds of both the real and imaginary parts of x, modifying x in-place.
```

#### 4.2.4 Input and output

The *acb\_print...* functions print to standard output, while *acb\_fprint...* functions print to the stream *file*.

```
void acb_print(const acb_t x)
void acb_fprint(FILE * file, const acb_t x)
    Prints the internal representation of x.
void acb_printd(const acb_t x, slong digits)
void acb_fprintd(FILE * file, const acb_t x, slong digits)
    Prints x in decimal. The printed value of the radius is not adjusted to compensate for the fact that
    the binary-to-decimal conversion of both the midpoint and the radius introduces additional error.
void acb_printn(const acb_t x, slong digits, ulong flags)
void acb_fprintn(FILE * file, const acb_t x, slong digits, ulong flags)
    Prints a nice decimal representation of x, using the format of arb_get_str() (or the corresponding
    arb_printn()) for the real and imaginary parts.
```

By default, the output shows the midpoint of both the real and imaginary parts with a guaranteed error of at most one unit in the last decimal place. In addition, explicit error bounds are printed so that the displayed decimal interval is guaranteed to enclose *x*.

Any flags understood by *arb\_get\_str()* can be passed via *flags* to control the format of the real and imaginary parts.

### 4.2.5 Random number generation

void **acb\_randtest**(*acb\_t* z, *flint\_rand\_t* state, *slong* prec, *slong* mag\_bits)  
 Generates a random complex number by generating separate random real and imaginary parts.

void **acb\_randtest\_special**(*acb\_t* z, *flint\_rand\_t* state, *slong* prec, *slong* mag\_bits)  
 Generates a random complex number by generating separate random real and imaginary parts.  
 Also generates NaNs and infinities.

void **acb\_randtest\_precise**(*acb\_t* z, *flint\_rand\_t* state, *slong* prec, *slong* mag\_bits)  
 Generates a random complex number with precise real and imaginary parts.

void **acb\_randtest\_param**(*acb\_t* z, *flint\_rand\_t* state, *slong* prec, *slong* mag\_bits)  
 Generates a random complex number, with very high probability of generating integers and half-integers.

### 4.2.6 Precision and comparisons

int **acb\_is\_zero**(const *acb\_t* z)  
 Returns nonzero iff *z* is zero.

int **acb\_is\_one**(const *acb\_t* z)  
 Returns nonzero iff *z* is exactly 1.

int **acb\_is\_finite**(const *acb\_t* z)  
 Returns nonzero iff *z* certainly is finite.

int **acb\_is\_exact**(const *acb\_t* z)  
 Returns nonzero iff *z* is exact.

int **acb\_is\_int**(const *acb\_t* z)  
 Returns nonzero iff *z* is an exact integer.

int **acb\_is\_int\_2exp\_si**(const *acb\_t* x, *slong* e)  
 Returns nonzero iff *z* exactly equals  $n2^e$  for some integer *n*.

int **acb\_equal**(const *acb\_t* x, const *acb\_t* y)  
 Returns nonzero iff *x* and *y* are identical as sets, i.e. if the real and imaginary parts are equal as balls.

Note that this is not the same thing as testing whether both *x* and *y* certainly represent the same complex number, unless either *x* or *y* is exact (and neither contains NaN). To test whether both operands *might* represent the same mathematical quantity, use **acb\_overlaps()** or **acb\_contains()**, depending on the circumstance.

int **acb\_equal\_si**(const *acb\_t* x, *slong* y)  
 Returns nonzero iff *x* is equal to the integer *y*.

int **acb\_eq**(const *acb\_t* x, const *acb\_t* y)  
 Returns nonzero iff *x* and *y* are certainly equal, as determined by testing that **arb\_eq()** holds for both the real and imaginary parts.

int **acb\_ne**(const *acb\_t* x, const *acb\_t* y)  
 Returns nonzero iff *x* and *y* are certainly not equal, as determined by testing that **arb\_ne()** holds for either the real or imaginary parts.

int **acb\_overlaps**(const *acb\_t* x, const *acb\_t* y)  
 Returns nonzero iff *x* and *y* have some point in common.

void **acb\_union**(*acb\_t* z, const *acb\_t* x, const *acb\_t* y, *slong* prec)  
 Sets *z* to a complex interval containing both *x* and *y*.

void **acb\_get\_abs\_ubound\_arf**(*arf\_t* u, const *acb\_t* z, *slong* prec)  
 Sets *u* to an upper bound for the absolute value of *z*, computed using a working precision of *prec* bits.

void **acb\_get\_abs\_lbound\_arf**(*arf\_t* u, const *acb\_t* z, *slong* prec)  
Sets *u* to a lower bound for the absolute value of *z*, computed using a working precision of *prec* bits.

void **acb\_get\_rad\_ubound\_arf**(*arf\_t* u, const *acb\_t* z, *slong* prec)  
Sets *u* to an upper bound for the error radius of *z* (the value is currently not computed tightly).

void **acb\_get\_mag**(*mag\_t* u, const *acb\_t* x)  
Sets *u* to an upper bound for the absolute value of *x*.

void **acb\_get\_mag\_lower**(*mag\_t* u, const *acb\_t* x)  
Sets *u* to a lower bound for the absolute value of *x*.

int **acb\_contains\_fmpq**(const *acb\_t* x, const *fmpq\_t* y)  
int **acb\_contains\_fmpz**(const *acb\_t* x, const *fmpz\_t* y)  
int **acb\_contains**(const *acb\_t* x, const *acb\_t* y)  
Returns nonzero iff *y* is contained in *x*.

int **acb\_contains\_zero**(const *acb\_t* x)  
Returns nonzero iff zero is contained in *x*.

int **acb\_contains\_int**(const *acb\_t* x)  
Returns nonzero iff the complex interval represented by *x* contains an integer.

*slong* **acb\_rel\_error\_bits**(const *acb\_t* x)  
Returns the effective relative error of *x* measured in bits. This is computed as if calling **arb\_rel\_error\_bits()** on the real ball whose midpoint is the larger out of the real and imaginary midpoints of *x*, and whose radius is the larger out of the real and imaginary radii of *x*.

*slong* **acb\_rel\_accuracy\_bits**(const *acb\_t* x)  
Returns the effective relative accuracy of *x* measured in bits, equal to the negative of the return value from **acb\_rel\_error\_bits()**.

*slong* **acb\_bits**(const *acb\_t* x)  
Returns the maximum of **arb\_bits** applied to the real and imaginary parts of *x*, i.e. the minimum precision sufficient to represent *x* exactly.

void **acb\_indeterminate**(*acb\_t* x)  
Sets *x* to  $[\text{NaN} \pm \infty] + [\text{NaN} \pm \infty]i$ , representing an indeterminate result.

void **acb\_trim**(*acb\_t* y, const *acb\_t* x)  
Sets *y* to a copy of *x* with both the real and imaginary parts trimmed (see **arb\_trim()**).

int **acb\_is\_real**(const *acb\_t* x)  
Returns nonzero iff the imaginary part of *x* is zero. It does not test whether the real part of *x* also is finite.

int **acb\_get\_unique\_fmpz**(*fmpz\_t* z, const *acb\_t* x)  
If *x* contains a unique integer, sets *z* to that value and returns nonzero. Otherwise (if *x* represents no integers or more than one integer), returns zero.

## 4.2.7 Complex parts

void **acb\_get\_real**(*arb\_t* re, const *acb\_t* z)  
Sets *re* to the real part of *z*.

void **acb\_get\_imag**(*arb\_t* im, const *acb\_t* z)  
Sets *im* to the imaginary part of *z*.

void **acb\_arg**(*arb\_t* r, const *acb\_t* z, *slong* prec)  
Sets *r* to a real interval containing the complex argument (phase) of *z*. We define the complex argument have a discontinuity on  $(-\infty, 0]$ , with the special value  $\arg(0) = 0$ , and  $\arg(a + 0i) = \pi$  for  $a < 0$ . Equivalently, if  $z = a + bi$ , the argument is given by  $\text{atan2}(b, a)$  (see **arb\_atan2()**).

void **acb\_abs**(*arb\_t* r, const *acb\_t* z, *slong prec*)  
 Sets *r* to the absolute value of *z*.

void **acb\_sgn**(*acb\_t* r, const *acb\_t* z, *slong prec*)  
 Sets *r* to the complex sign of *z*, defined as 0 if *z* is exactly zero and the projection onto the unit circle  $z/|z| = \exp(i \arg(z))$  otherwise.

void **acb\_csgn**(*arb\_t* r, const *acb\_t* z)  
 Sets *r* to the extension of the real sign function taking the value 1 for *z* strictly in the right half plane, -1 for *z* strictly in the left half plane, and the sign of the imaginary part when *z* is on the imaginary axis. Equivalently,  $\text{csgn}(z) = z/\sqrt{z^2}$  except that the value is 0 when *z* is exactly zero.

## 4.2.8 Arithmetic

void **acb\_neg**(*acb\_t* z, const *acb\_t* x)  
 Sets *z* to the negation of *x*.

void **acb\_conj**(*acb\_t* z, const *acb\_t* x)  
 Sets *z* to the complex conjugate of *x*.

void **acb\_add\_ui**(*acb\_t* z, const *acb\_t* x, *ulong y*, *slong prec*)

void **acb\_add\_si**(*acb\_t* z, const *acb\_t* x, *slong y*, *slong prec*)

void **acb\_add\_fmpz**(*acb\_t* z, const *acb\_t* x, const *fmpz\_t* y, *slong prec*)

void **acb\_add\_arb**(*acb\_t* z, const *acb\_t* x, const *arb\_t* y, *slong prec*)

void **acb\_add**(*acb\_t* z, const *acb\_t* x, const *acb\_t* y, *slong prec*)  
 Sets *z* to the sum of *x* and *y*.

void **acb\_sub\_ui**(*acb\_t* z, const *acb\_t* x, *ulong y*, *slong prec*)

void **acb\_sub\_si**(*acb\_t* z, const *acb\_t* x, *slong y*, *slong prec*)

void **acb\_sub\_fmpz**(*acb\_t* z, const *acb\_t* x, const *fmpz\_t* y, *slong prec*)

void **acb\_sub\_arb**(*acb\_t* z, const *acb\_t* x, const *arb\_t* y, *slong prec*)

void **acb\_sub**(*acb\_t* z, const *acb\_t* x, const *acb\_t* y, *slong prec*)  
 Sets *z* to the difference of *x* and *y*.

void **acb\_mul\_onei**(*acb\_t* z, const *acb\_t* x)  
 Sets *z* to *x* multiplied by the imaginary unit.

void **acb\_div\_onei**(*acb\_t* z, const *acb\_t* x)  
 Sets *z* to *x* divided by the imaginary unit.

void **acb\_mul\_ui**(*acb\_t* z, const *acb\_t* x, *ulong y*, *slong prec*)

void **acb\_mul\_si**(*acb\_t* z, const *acb\_t* x, *slong y*, *slong prec*)

void **acb\_mul\_fmpz**(*acb\_t* z, const *acb\_t* x, const *fmpz\_t* y, *slong prec*)

void **acb\_mul\_arb**(*acb\_t* z, const *acb\_t* x, const *arb\_t* y, *slong prec*)  
 Sets *z* to the product of *x* and *y*.

void **acb\_mul**(*acb\_t* z, const *acb\_t* x, const *acb\_t* y, *slong prec*)  
 Sets *z* to the product of *x* and *y*. If at least one part of *x* or *y* is zero, the operations is reduced to two real multiplications. If *x* and *y* are the same pointers, they are assumed to represent the same mathematical quantity and the squaring formula is used.

void **acb\_mul\_2exp\_si**(*acb\_t* z, const *acb\_t* x, *slong e*)

void **acb\_mul\_2exp\_fmpz**(*acb\_t* z, const *acb\_t* x, const *fmpz\_t* e)  
 Sets *z* to *x* multiplied by  $2^e$ , without rounding.

void **acb\_sqr**(*acb\_t* z, const *acb\_t* x, *slong prec*)  
 Sets *z* to *x* squared.

void **acb\_cube**(*acb\_t* z, const *acb\_t* x, *slong* prec)  
Sets  $z$  to  $x$  cubed, computed efficiently using two real squarings, two real multiplications, and scalar operations.

void **acb\_addmul**(*acb\_t* z, const *acb\_t* x, const *acb\_t* y, *slong* prec)

void **acb\_addmul\_ui**(*acb\_t* z, const *acb\_t* x, *ulong* y, *slong* prec)

void **acb\_addmul\_si**(*acb\_t* z, const *acb\_t* x, *slong* y, *slong* prec)

void **acb\_addmul\_fmpz**(*acb\_t* z, const *acb\_t* x, const *fmpz\_t* y, *slong* prec)

void **acb\_addmul\_arb**(*acb\_t* z, const *acb\_t* x, const *arb\_t* y, *slong* prec)  
Sets  $z$  to  $z$  plus the product of  $x$  and  $y$ .

void **acb\_submul**(*acb\_t* z, const *acb\_t* x, const *acb\_t* y, *slong* prec)

void **acb\_submul\_ui**(*acb\_t* z, const *acb\_t* x, *ulong* y, *slong* prec)

void **acb\_submul\_si**(*acb\_t* z, const *acb\_t* x, *slong* y, *slong* prec)

void **acb\_submul\_fmpz**(*acb\_t* z, const *acb\_t* x, const *fmpz\_t* y, *slong* prec)

void **acb\_submul\_arb**(*acb\_t* z, const *acb\_t* x, const *arb\_t* y, *slong* prec)  
Sets  $z$  to  $z$  minus the product of  $x$  and  $y$ .

void **acb\_inv**(*acb\_t* z, const *acb\_t* x, *slong* prec)  
Sets  $z$  to the multiplicative inverse of  $x$ .

void **acb\_div\_ui**(*acb\_t* z, const *acb\_t* x, *ulong* y, *slong* prec)

void **acb\_div\_si**(*acb\_t* z, const *acb\_t* x, *slong* y, *slong* prec)

void **acb\_div\_fmpz**(*acb\_t* z, const *acb\_t* x, const *fmpz\_t* y, *slong* prec)

void **acb\_div\_arb**(*acb\_t* z, const *acb\_t* x, const *arb\_t* y, *slong* prec)

void **acb\_div**(*acb\_t* z, const *acb\_t* x, const *acb\_t* y, *slong* prec)  
Sets  $z$  to the quotient of  $x$  and  $y$ .

## 4.2.9 Mathematical constants

void **acb\_const\_pi**(*acb\_t* y, *slong* prec)  
Sets  $y$  to the constant  $\pi$ .

## 4.2.10 Powers and roots

void **acb\_sqrt**(*acb\_t* r, const *acb\_t* z, *slong* prec)  
Sets  $r$  to the square root of  $z$ . If either the real or imaginary part is exactly zero, only a single real square root is needed. Generally, we use the formula  $\sqrt{a+bi} = u/2 + ib/u$ ,  $u = \sqrt{2(|a+bi|+a)}$ , requiring two real square root extractions.

void **acb\_rsqrt**(*acb\_t* r, const *acb\_t* z, *slong* prec)  
Sets  $r$  to the reciprocal square root of  $z$ . If either the real or imaginary part is exactly zero, only a single real reciprocal square root is needed. Generally, we use the formula  $1/\sqrt{a+bi} = ((a+r) - bi)/v$ ,  $r = |a+bi|$ ,  $v = \sqrt{r|a+bi+r|^2}$ , requiring one real square root and one real reciprocal square root.

void **acb\_quadratic\_roots\_fmpz**(*acb\_t* r1, *acb\_t* r2, const *fmpz\_t* a, const *fmpz\_t* b, const *fmpz\_t* c, *slong* prec)  
Sets  $r1$  and  $r2$  to the roots of the quadratic polynomial  $ax^2 + bx + c$ . Requires that  $a$  is nonzero. This function is implemented so that both roots are computed accurately even when direct use of the quadratic formula would lose accuracy.

void **acb\_root\_ui**(*acb\_t* r, const *acb\_t* z, *ulong* k, *slong* prec)  
Sets  $r$  to the principal  $k$ -th root of  $z$ .

```
void acb_pow_fmpz(acb_t y, const acb_t b, const fmpz_t e, slong prec)
void acb_pow_ui(acb_t y, const acb_t b, ulong e, slong prec)
void acb_pow_si(acb_t y, const acb_t b, slong e, slong prec)
    Sets  $y = b^e$  using binary exponentiation (with an initial division if  $e < 0$ ). Note that these functions
    can get slow if the exponent is extremely large (in such cases acb_pow() may be superior).
void acb_pow_arb(acb_t z, const acb_t x, const arb_t y, slong prec)
void acb_pow(acb_t z, const acb_t x, const acb_t y, slong prec)
    Sets  $z = x^y$ , computed using binary exponentiation if  $y$  is a small exact integer, as  $z = (x^{1/2})^{2y}$  if
     $y$  is a small exact half-integer, and generally as  $z = \exp(y \log x)$ .
void acb_unit_root(acb_t res, ulong order, slong prec)
    Sets  $res$  to  $\exp(\frac{2i\pi}{order})$  to precision  $prec$ .
```

#### 4.2.11 Exponentials and logarithms

```
void acb_exp(acb_t y, const acb_t z, slong prec)
    Sets  $y$  to the exponential function of  $z$ , computed as  $\exp(a + bi) = \exp(a) (\cos(b) + \sin(b)i)$ .
void acb_exp_pi_i(acb_t y, const acb_t z, slong prec)
    Sets  $y$  to  $\exp(\pi iz)$ .
void acb_exp_invexp(acb_t s, acb_t t, const acb_t z, slong prec)
    Sets  $v = \exp(z)$  and  $w = \exp(-z)$ .
void acb_expm1(acb_t res, const acb_t z, slong prec)
    Computes  $\exp(z) - 1$ , using an accurate method when  $z \approx 0$ .
void acb_log(acb_t y, const acb_t z, slong prec)
    Sets  $y$  to the principal branch of the natural logarithm of  $z$ , computed as  $\log(a + bi) = \frac{1}{2} \log(a^2 + b^2) + i \arg(a + bi)$ .
void acb_log1p(acb_t z, const acb_t x, slong prec)
    Sets  $z = \log(1 + x)$ , computed accurately when  $x \approx 0$ .
```

#### 4.2.12 Trigonometric functions

```
void acb_sin(acb_t s, const acb_t z, slong prec)
void acb_cos(acb_t c, const acb_t z, slong prec)
void acb_sin_cos(acb_t s, acb_t c, const acb_t z, slong prec)
    Sets  $s = \sin(z)$ ,  $c = \cos(z)$ , evaluated as  $\sin(a + bi) = \sin(a) \cosh(b) + i \cos(a) \sinh(b)$ ,  $\cos(a + bi) = \cos(a) \cosh(b) - i \sin(a) \sinh(b)$ .
void acb_tan(acb_t s, const acb_t z, slong prec)
    Sets  $s = \tan(z) = \sin(z)/\cos(z)$ . For large imaginary parts, the function is evaluated in a numerically
    stable way as  $\pm i$  plus a decreasing exponential factor.
void acb_cot(acb_t s, const acb_t z, slong prec)
    Sets  $s = \cot(z) = \cos(z)/\sin(z)$ . For large imaginary parts, the function is evaluated in a numerically
    stable way as  $\pm i$  plus a decreasing exponential factor.
void acb_sin_pi(acb_t s, const acb_t z, slong prec)
void acb_cos_pi(acb_t c, const acb_t z, slong prec)
void acb_sin_cos_pi(acb_t s, acb_t c, const acb_t z, slong prec)
    Sets  $s = \sin(\pi z)$ ,  $c = \cos(\pi z)$ , evaluating the trigonometric factors of the real and imaginary part
    accurately via arb_sin_cos_pi().
```

void **acb\_tan\_pi**(*acb\_t* s, const *acb\_t* z, *slong* prec)  
Sets  $s = \tan(\pi z)$ . Uses the same algorithm as **acb\_tan()**, but evaluates the sine and cosine accurately via **arb\_sin\_cos\_pi()**.

void **acb\_cot\_pi**(*acb\_t* s, const *acb\_t* z, *slong* prec)  
Sets  $s = \cot(\pi z)$ . Uses the same algorithm as **acb\_cot()**, but evaluates the sine and cosine accurately via **arb\_sin\_cos\_pi()**.

void **acb\_sinc**(*acb\_t* s, const *acb\_t* z, *slong* prec)  
Sets  $s = \text{sinc}(x) = \sin(z)/z$ .

void **acb\_sinc\_pi**(*acb\_t* s, const *acb\_t* z, *slong* prec)  
Sets  $s = \text{sinc}(\pi x) = \sin(\pi z)/(\pi z)$ .

## 4.2.13 Inverse trigonometric functions

void **acb\_asin**(*acb\_t* res, const *acb\_t* z, *slong* prec)  
Sets  $res$  to  $\text{asin}(z) = -i \log(iz + \sqrt{1 - z^2})$ .

void **acb\_acos**(*acb\_t* res, const *acb\_t* z, *slong* prec)  
Sets  $res$  to  $\text{acos}(z) = \frac{1}{2}\pi - \text{asin}(z)$ .

void **acb\_atan**(*acb\_t* res, const *acb\_t* z, *slong* prec)  
Sets  $res$  to  $\text{atan}(z) = \frac{1}{2}i(\log(1 - iz) - \log(1 + iz))$ .

## 4.2.14 Hyperbolic functions

void **acb\_sinh**(*acb\_t* s, const *acb\_t* z, *slong* prec)

void **acb\_cosh**(*acb\_t* c, const *acb\_t* z, *slong* prec)

void **acb\_sinh\_cosh**(*acb\_t* s, *acb\_t* c, const *acb\_t* z, *slong* prec)

void **acb\_tanh**(*acb\_t* s, const *acb\_t* z, *slong* prec)

void **acb\_coth**(*acb\_t* s, const *acb\_t* z, *slong* prec)  
Respectively computes  $\sinh(z) = -i \sin(iz)$ ,  $\cosh(z) = \cos(iz)$ ,  $\tanh(z) = -i \tan(iz)$ ,  $\coth(z) = i \cot(iz)$ .

## 4.2.15 Inverse hyperbolic functions

void **acb\_asinh**(*acb\_t* res, const *acb\_t* z, *slong* prec)  
Sets  $res$  to  $\text{asinh}(z) = -i \text{asin}(iz)$ .

void **acb\_acosh**(*acb\_t* res, const *acb\_t* z, *slong* prec)  
Sets  $res$  to  $\text{acosh}(z) = \log(z + \sqrt{z + 1}\sqrt{z - 1})$ .

void **acb\_atanh**(*acb\_t* res, const *acb\_t* z, *slong* prec)  
Sets  $res$  to  $\text{atanh}(z) = -i \text{atan}(iz)$ .

## 4.2.16 Lambert W function

void **acb\_lambertw\_asymp**(*acb\_t* res, const *acb\_t* z, const *fmpz\_t* k, *slong* L, *slong* M, *slong* prec)  
Sets  $res$  to the Lambert W function  $W_k(z)$  computed using  $L$  and  $M$  terms in the bivariate series giving the asymptotic expansion at zero or infinity. This algorithm is valid everywhere, but the error bound is only finite when  $|\log(z)|$  is sufficiently large.

int **acb\_lambertw\_check\_branch**(const *acb\_t* w, const *fmpz\_t* k, *slong* prec)  
Tests if  $w$  definitely lies in the image of the branch  $W_k(z)$ . This function is used internally to verify that a computed approximation of the Lambert W function lies on the intended branch. Note that

this will necessarily evaluate to false for points exactly on (or overlapping) the branch cuts, where a different algorithm has to be used.

void **acb\_lambertw\_bound\_deriv**(*mag\_t* res, const *acb\_t* z, const *acb\_t* ez1, const *fmpz\_t* k)  
Sets *res* to an upper bound for  $|W'_k(z)|$ . The input *ez1* should contain the precomputed value of  $ez + 1$ .

Along the real line, the directional derivative of  $W_k(z)$  is understood to be taken. As a result, the user must handle the branch cut discontinuity separately when using this function to bound perturbations in the value of  $W_k(z)$ .

void **acb\_lambertw**(*acb\_t* res, const *acb\_t* z, const *fmpz\_t* k, int flags, *slong* prec)  
Sets *res* to the Lambert W function  $W_k(z)$  where the index *k* selects the branch (with  $k = 0$  giving the principal branch). The placement of branch cuts follows [CGHJK1996].

If *flags* is nonzero, nonstandard branch cuts are used.

If *flags* is set to `ACB_LAMBERTW_LEFT`, computes  $W_{\text{left}|k}(z)$  which corresponds to  $W_k(z)$  in the upper half plane and  $W_{k+1}(z)$  in the lower half plane, connected continuously to the left of the branch points. In other words, the branch cut on  $(-\infty, 0)$  is rotated counterclockwise to  $(0, +\infty)$ . (For  $k = -1$  and  $k = 0$ , there is also a branch cut on  $(-1/e, 0)$ , continuous from below instead of from above to maintain counterclockwise continuity.)

If *flags* is set to `ACB_LAMBERTW_MIDDLE`, computes  $W_{\text{middle}}(z)$  which corresponds to  $W_{-1}(z)$  in the upper half plane and  $W_1(z)$  in the lower half plane, connected continuously through  $(-1/e, 0)$  with branch cuts on  $(-\infty, -1/e)$  and  $(0, +\infty)$ .  $W_{\text{middle}}(z)$  extends the real analytic function  $W_{-1}(x)$  defined on  $(-1/e, 0)$  to a complex analytic function, whereas the standard branch  $W_{-1}(z)$  has a branch cut along the real segment.

The algorithm used to compute the Lambert W function is described in [Joh2017b].

#### 4.2.17 Rising factorials

void **acb\_rising\_ui\_bs**(*acb\_t* z, const *acb\_t* x, *ulong* n, *slong* prec)

void **acb\_rising\_ui\_rs**(*acb\_t* z, const *acb\_t* x, *ulong* n, *ulong* step, *slong* prec)

void **acb\_rising\_ui\_rec**(*acb\_t* z, const *acb\_t* x, *ulong* n, *slong* prec)

void **acb\_rising\_ui**(*acb\_t* z, const *acb\_t* x, *ulong* n, *slong* prec)

void **acb\_rising**(*acb\_t* z, const *acb\_t* x, const *acb\_t* n, *slong* prec)  
Computes the rising factorial  $z = x(x+1)(x+2)\cdots(x+n-1)$ .

The *bs* version uses binary splitting. The *rs* version uses rectangular splitting. The *rec* version uses either *bs* or *rs* depending on the input. The default version uses the gamma function unless *n* is a small integer.

The *rs* version takes an optional *step* parameter for tuning purposes (to use the default step length, pass zero).

void **acb\_rising2\_ui\_bs**(*acb\_t* u, *acb\_t* v, const *acb\_t* x, *ulong* n, *slong* prec)

void **acb\_rising2\_ui\_rs**(*acb\_t* u, *acb\_t* v, const *acb\_t* x, *ulong* n, *ulong* step, *slong* prec)

void **acb\_rising2\_ui**(*acb\_t* u, *acb\_t* v, const *acb\_t* x, *ulong* n, *slong* prec)

Letting  $u(x) = x(x+1)(x+2)\cdots(x+n-1)$ , simultaneously compute  $u(x)$  and  $v(x) = u'(x)$ , respectively using binary splitting, rectangular splitting (with optional nonzero step length *step* to override the default choice), and an automatic algorithm choice.

void **acb\_rising\_ui\_get\_mag**(*mag\_t* bound, const *acb\_t* x, *ulong* n)

Computes an upper bound for the absolute value of the rising factorial  $z = x(x+1)(x+2)\cdots(x+n-1)$ . Not currently optimized for large *n*.

## 4.2.18 Gamma function

void **acb\_gamma**(*acb\_t* y, const *acb\_t* x, *slong* prec)

Computes the gamma function  $y = \Gamma(x)$ .

void **acb\_rgamma**(*acb\_t* y, const *acb\_t* x, *slong* prec)

Computes the reciprocal gamma function  $y = 1/\Gamma(x)$ , avoiding division by zero at the poles of the gamma function.

void **acb\_lgamma**(*acb\_t* y, const *acb\_t* x, *slong* prec)

Computes the logarithmic gamma function  $y = \log \Gamma(x)$ .

The branch cut of the logarithmic gamma function is placed on the negative half-axis, which means that  $\log \Gamma(z) + \log z = \log \Gamma(z+1)$  holds for all  $z$ , whereas  $\log \Gamma(z) \neq \log(\Gamma(z))$  in general. In the left half plane, the reflection formula with correct branch structure is evaluated via [`acb\_log\_sin\_pi\(\)`](#).

void **acb\_digamma**(*acb\_t* y, const *acb\_t* x, *slong* prec)

Computes the digamma function  $y = \psi(x) = (\log \Gamma(x))' = \Gamma'(x)/\Gamma(x)$ .

void **acb\_log\_sin\_pi**(*acb\_t* res, const *acb\_t* z, *slong* prec)

Computes the logarithmic sine function defined by

$$S(z) = \log(\pi) - \log \Gamma(z) + \log \Gamma(1 - z)$$

which is equal to

$$S(z) = \int_{1/2}^z \pi \cot(\pi t) dt$$

where the path of integration goes through the upper half plane if  $0 < \arg(z) \leq \pi$  and through the lower half plane if  $-\pi < \arg(z) \leq 0$ . Equivalently,

$$S(z) = \log(\sin(\pi(z - n))) \mp n\pi i, \quad n = \lfloor \operatorname{re}(z) \rfloor$$

where the negative sign is taken if  $0 < \arg(z) \leq \pi$  and the positive sign is taken otherwise (if the interval  $\arg(z)$  does not certainly satisfy either condition, the union of both cases is computed). After subtracting  $n$ , we have  $0 \leq \operatorname{re}(z) < 1$ . In this strip, we use  $S(z) = \log(\sin(\pi(z)))$  if the imaginary part of  $z$  is small. Otherwise, we use  $S(z) = i\pi(z - 1/2) + \log((1 + e^{-2i\pi z})/2)$  in the lower half-plane and the conjugated expression in the upper half-plane to avoid exponent overflow.

The function is evaluated at the midpoint and the propagated error is computed from  $S'(z)$  to get a continuous change when  $z$  is non-real and  $n$  spans more than one possible integer value.

void **acb\_polygamma**(*acb\_t* z, const *acb\_t* s, const *acb\_t* z, *slong* prec)

Sets *res* to the value of the generalized polygamma function  $\psi(s, z)$ .

If  $s$  is a nonnegative order, this is simply the  $s$ -order derivative of the digamma function. If  $s = 0$ , this function simply calls the digamma function internally. For integers  $s \geq 1$ , it calls the Hurwitz zeta function. Note that for small integers  $s \geq 1$ , it can be faster to use [`acb\_poly\_digamma\_series\(\)`](#) and read off the coefficients.

The generalization to other values of  $s$  is due to Espinosa and Moll [\[EM2004\]](#):

$$\psi(s, z) = \frac{\zeta'(s+1, z) + (\gamma + \psi(-s))\zeta(s+1, z)}{\Gamma(-s)}$$

void **acb\_barnes\_g**(*acb\_t* res, const *acb\_t* z, *slong* prec)

void **acb\_log\_barnes\_g**(*acb\_t* res, const *acb\_t* z, *slong* prec)

Computes Barnes  $G$ -function or the logarithmic Barnes  $G$ -function, respectively. The logarithmic version has branch cuts on the negative real axis and is continuous elsewhere in the complex plane, in analogy with the logarithmic gamma function. The functional equation

$$\log G(z+1) = \log \Gamma(z) + \log G(z).$$

holds for all  $z$ .

For small integers, we directly use the recurrence relation  $G(z+1) = \Gamma(z)G(z)$  together with the initial value  $G(1) = 1$ . For general  $z$ , we use the formula

$$\log G(z) = (z-1) \log \Gamma(z) - \zeta'(-1, z) + \zeta'(-1).$$

#### 4.2.19 Zeta function

void **acb\_zeta**(*acb\_t*  $z$ , const *acb\_t*  $s$ , *slong*  $prec$ )

Sets  $z$  to the value of the Riemann zeta function  $\zeta(s)$ . Note: for computing derivatives with respect to  $s$ , use *acb\_poly\_zeta\_series()* or related methods.

This is a wrapper of *acb\_dirichlet\_zeta()*.

void **acb\_hurwitz\_zeta**(*acb\_t*  $z$ , const *acb\_t*  $s$ , const *acb\_t*  $a$ , *slong*  $prec$ )

Sets  $z$  to the value of the Hurwitz zeta function  $\zeta(s, a)$ . Note: for computing derivatives with respect to  $s$ , use *acb\_poly\_zeta\_series()* or related methods.

This is a wrapper of *acb\_dirichlet\_hurwitz()*.

void **acb\_bernoulli\_poly\_ui**(*acb\_t*  $res$ , *ulong*  $n$ , const *acb\_t*  $x$ , *slong*  $prec$ )

Sets  $res$  to the value of the Bernoulli polynomial  $B_n(x)$ .

Warning: this function is only fast if either  $n$  or  $x$  is a small integer.

This function reads Bernoulli numbers from the global cache if they are already cached, but does not automatically extend the cache by itself.

#### 4.2.20 Polylogarithms

void **acb\_polylog**(*acb\_t*  $w$ , const *acb\_t*  $s$ , const *acb\_t*  $z$ , *slong*  $prec$ )

void **acb\_polylog\_si**(*acb\_t*  $w$ , *slong*  $s$ , const *acb\_t*  $z$ , *slong*  $prec$ )

Sets  $w$  to the polylogarithm  $\text{Li}_s(z)$ .

#### 4.2.21 Arithmetic-geometric mean

See *Algorithms for the arithmetic-geometric mean* for implementation details.

void **acb\_agm1**(*acb\_t*  $m$ , const *acb\_t*  $z$ , *slong*  $prec$ )

Sets  $m$  to the arithmetic-geometric mean  $M(z) = \text{agm}(1, z)$ , defined such that the function is continuous in the complex plane except for a branch cut along the negative half axis (where it is continuous from above). This corresponds to always choosing an “optimal” branch for the square root in the arithmetic-geometric mean iteration.

void **acb\_agm1\_cpx**(*acb\_ptr*  $m$ , const *acb\_t*  $z$ , *slong*  $len$ , *slong*  $prec$ )

Sets the coefficients in the array  $m$  to the power series expansion of the arithmetic-geometric mean at the point  $z$  truncated to length  $len$ , i.e.  $M(z+x) \in \mathbb{C}[[x]]$ .

#### 4.2.22 Other special functions

void **acb\_chebyshev\_t\_ui**(*acb\_t*  $a$ , *ulong*  $n$ , const *acb\_t*  $x$ , *slong*  $prec$ )

void **acb\_chebyshev\_u\_ui**(*acb\_t*  $a$ , *ulong*  $n$ , const *acb\_t*  $x$ , *slong*  $prec$ )

Evaluates the Chebyshev polynomial of the first kind  $a = T_n(x)$  or the Chebyshev polynomial of the second kind  $a = U_n(x)$ .

void **acb\_chebyshev\_t2\_ui**(*acb\_t*  $a$ , *acb\_t*  $b$ , *ulong*  $n$ , const *acb\_t*  $x$ , *slong*  $prec$ )

void **acb\_chebyshev\_u2\_ui**(*acb\_t* a, *acb\_t* b, *ulong* n, const *acb\_t* x, *slong* prec)  
Simultaneously evaluates  $a = T_n(x)$ ,  $b = T_{n-1}(x)$  or  $a = U_n(x)$ ,  $b = U_{n-1}(x)$ . Aliasing between *a*, *b* and *x* is not permitted.

## 4.2.23 Vector functions

void **\_acb\_vec\_zero**(*acb\_ptr* A, *slong* n)  
Sets all entries in *vec* to zero.

int **\_acb\_vec\_is\_zero**(*acb\_srcptr* vec, *slong* len)  
Returns nonzero iff all entries in *x* are zero.

int **\_acb\_vec\_is\_real**(*acb\_srcptr* v, *slong* len)  
Returns nonzero iff all entries in *x* have zero imaginary part.

void **\_acb\_vec\_set**(*acb\_ptr* res, *acb\_srcptr* vec, *slong* len)  
Sets *res* to a copy of *vec*.

void **\_acb\_vec\_set\_round**(*acb\_ptr* res, *acb\_srcptr* vec, *slong* len, *slong* prec)  
Sets *res* to a copy of *vec*, rounding each entry to *prec* bits.

void **\_acb\_vec\_neg**(*acb\_ptr* res, *acb\_srcptr* vec, *slong* len)

void **\_acb\_vec\_add**(*acb\_ptr* res, *acb\_srcptr* vec1, *acb\_srcptr* vec2, *slong* len, *slong* prec)

void **\_acb\_vec\_sub**(*acb\_ptr* res, *acb\_srcptr* vec1, *acb\_srcptr* vec2, *slong* len, *slong* prec)

void **\_acb\_vec\_scalar\_submul**(*acb\_ptr* res, *acb\_srcptr* vec, *slong* len, const *acb\_t* c, *slong* prec)

void **\_acb\_vec\_scalar\_addmul**(*acb\_ptr* res, *acb\_srcptr* vec, *slong* len, const *acb\_t* c, *slong* prec)

void **\_acb\_vec\_scalar\_mul**(*acb\_ptr* res, *acb\_srcptr* vec, *slong* len, const *acb\_t* c, *slong* prec)

void **\_acb\_vec\_scalar\_mul\_ui**(*acb\_ptr* res, *acb\_srcptr* vec, *slong* len, *ulong* c, *slong* prec)

void **\_acb\_vec\_scalar\_mul\_2exp\_si**(*acb\_ptr* res, *acb\_srcptr* vec, *slong* len, *slong* c)

void **\_acb\_vec\_scalar\_mul\_onei**(*acb\_ptr* res, *acb\_srcptr* vec, *slong* len)

void **\_acb\_vec\_scalar\_div\_ui**(*acb\_ptr* res, *acb\_srcptr* vec, *slong* len, *ulong* c, *slong* prec)

void **\_acb\_vec\_scalar\_div**(*acb\_ptr* res, *acb\_srcptr* vec, *slong* len, const *acb\_t* c, *slong* prec)

void **\_acb\_vec\_scalar\_mul\_arb**(*acb\_ptr* res, *acb\_srcptr* vec, *slong* len, const *arb\_t* c, *slong* prec)

void **\_acb\_vec\_scalar\_div\_arb**(*acb\_ptr* res, *acb\_srcptr* vec, *slong* len, const *arb\_t* c, *slong* prec)

void **\_acb\_vec\_scalar\_mul\_fmpz**(*acb\_ptr* res, *acb\_srcptr* vec, *slong* len, const *fmpz\_t* c, *slong* prec)

void **\_acb\_vec\_scalar\_div\_fmpz**(*acb\_ptr* res, *acb\_srcptr* vec, *slong* len, const *fmpz\_t* c, *slong* prec)  
Performs the respective scalar operation elementwise.

*slong* **\_acb\_vec\_bits**(*acb\_srcptr* vec, *slong* len)  
Returns the maximum of **arb\_bits()** for all entries in *vec*.

void **\_acb\_vec\_set\_powers**(*acb\_ptr* xs, const *acb\_t* x, *slong* len, *slong* prec)  
Sets *xs* to the powers  $1, x, x^2, \dots, x^{len-1}$ .

void **\_acb\_vec\_unit\_roots**(*acb\_ptr* z, *slong* order, *slong* prec)  
Sets *z* to the powers  $1, z, z^2, \dots, z^{order-1}$  where  $z = \exp(\frac{2i\pi}{order})$  to precision *prec*.  
In order to avoid precision loss, this function does not simply compute powers of a primitive root.

void **\_acb\_vec\_add\_error\_arf\_vec**(*acb\_ptr* res, *arf\_srcptr* err, *slong* len)

void **\_acb\_vec\_add\_error\_mag\_vec**(*acb\_ptr* res, *mag\_srcptr* err, *slong* len)  
Adds the magnitude of each entry in *err* to the radius of the corresponding entry in *res*.

void **\_acb\_vec\_indeterminate**(*acb\_ptr* *vec*, *slong* *len*)

Applies *acb\_indeterminate()* elementwise.

void **\_acb\_vec\_trim**(*acb\_ptr* *res*, *acb\_srcptr* *vec*, *slong* *len*)

Applies *acb\_trim()* elementwise.

int **\_acb\_vec\_get\_unique\_fmpz\_vec**(fmpz \* *res*, *acb\_srcptr* *vec*, *slong* *len*)

Calls *acb\_get\_unique\_fmpz()* elementwise and returns nonzero if all entries can be rounded uniquely to integers. If any entry in *vec* cannot be rounded uniquely to an integer, returns zero.

void **\_acb\_vec\_sort\_pretty**(*acb\_ptr* *vec*, *slong* *len*)

Sorts the vector of complex numbers based on the real and imaginary parts. This is intended to reveal structure when printing a set of complex numbers, not to apply an order relation in a rigorous way.

## POLYNOMIALS AND POWER SERIES

These modules implement dense univariate polynomials with real and complex coefficients. Truncated power series are supported via methods acting on polynomials, without introducing a separate power series type.

### 5.1 `arb_poly.h` – polynomials over the real numbers

An `arb_poly_t` represents a polynomial over the real numbers, implemented as an array of coefficients of type `arb_struct`.

Most functions are provided in two versions: an underscore method which operates directly on pre-allocated arrays of coefficients and generally has some restrictions (such as requiring the lengths to be nonzero and not supporting aliasing of the input and output arrays), and a non-underscore method which performs automatic memory management and handles degenerate cases.

#### 5.1.1 Types, macros and constants

`arb_poly_struct`

`arb_poly_t`

Contains a pointer to an array of coefficients (`coeffs`), the used length (`length`), and the allocated size of the array (`alloc`).

An `arb_poly_t` is defined as an array of length one of type `arb_poly_struct`, permitting an `arb_poly_t` to be passed by reference.

#### 5.1.2 Memory management

void `arb_poly_init(arb_poly_t poly)`

Initializes the polynomial for use, setting it to the zero polynomial.

void `arb_poly_clear(arb_poly_t poly)`

Clears the polynomial, deallocating all coefficients and the coefficient array.

void `arb_poly_fit_length(arb_poly_t poly, slong len)`

Makes sure that the coefficient array of the polynomial contains at least `len` initialized coefficients.

void `_arb_poly_set_length(arb_poly_t poly, slong len)`

Directly changes the length of the polynomial, without allocating or deallocating coefficients. The value should not exceed the allocation length.

void `_arb_poly_normalise(arb_poly_t poly)`

Strips any trailing coefficients which are identical to zero.

*slong* `arb_poly_allocated_bytes(const arb_poly_t x)`

Returns the total number of bytes heap-allocated internally by this object. The count excludes

the size of the structure itself. Add `sizeof(arb_poly_struct)` to get the size of the object as a whole.

### 5.1.3 Basic manipulation

*slong* **arb\_poly\_length**(const *arb\_poly\_t* *poly*)

Returns the length of *poly*, i.e. zero if *poly* is identically zero, and otherwise one more than the index of the highest term that is not identically zero.

*slong* **arb\_poly\_degree**(const *arb\_poly\_t* *poly*)

Returns the degree of *poly*, defined as one less than its length. Note that if one or several leading coefficients are balls containing zero, this value can be larger than the true degree of the exact polynomial represented by *poly*, so the return value of this function is effectively an upper bound.

int **arb\_poly\_is\_zero**(const *arb\_poly\_t* *poly*)

int **arb\_poly\_is\_one**(const *arb\_poly\_t* *poly*)

int **arb\_poly\_is\_x**(const *arb\_poly\_t* *poly*)

Returns 1 if *poly* is exactly the polynomial 0, 1 or  $x$  respectively. Returns 0 otherwise.

void **arb\_poly\_zero**(*arb\_poly\_t* *poly*)

void **arb\_poly\_one**(*arb\_poly\_t* *poly*)

Sets *poly* to the constant 0 respectively 1.

void **arb\_poly\_set**(*arb\_poly\_t* *dest*, const *arb\_poly\_t* *src*)

Sets *dest* to a copy of *src*.

void **arb\_poly\_set\_round**(*arb\_poly\_t* *dest*, const *arb\_poly\_t* *src*, *slong* *prec*)

Sets *dest* to a copy of *src*, rounded to *prec* bits.

void **arb\_poly\_set\_trunc**(*arb\_poly\_t* *dest*, const *arb\_poly\_t* *src*, *slong* *n*)

void **arb\_poly\_set\_trunc\_round**(*arb\_poly\_t* *dest*, const *arb\_poly\_t* *src*, *slong* *n*, *slong* *prec*)

Sets *dest* to a copy of *src*, truncated to length *n* and rounded to *prec* bits.

void **arb\_poly\_set\_coeff\_si**(*arb\_poly\_t* *poly*, *slong* *n*, *slong* *c*)

void **arb\_poly\_set\_coeff\_arb**(*arb\_poly\_t* *poly*, *slong* *n*, const *arb\_t* *c*)

Sets the coefficient with index *n* in *poly* to the value *c*. We require that *n* is nonnegative.

void **arb\_poly\_get\_coeff\_arb**(*arb\_t* *v*, const *arb\_poly\_t* *poly*, *slong* *n*)

Sets *v* to the value of the coefficient with index *n* in *poly*. We require that *n* is nonnegative.

**arb\_poly\_get\_coeff\_ptr**(*poly*, *n*)

Given  $n \geq 0$ , returns a pointer to coefficient *n* of *poly*, or *NULL* if *n* exceeds the length of *poly*.

void **\_arb\_poly\_shift\_right**(*arb\_ptr* *res*, *arb\_srcptr* *poly*, *slong* *len*, *slong* *n*)

void **arb\_poly\_shift\_right**(*arb\_poly\_t* *res*, const *arb\_poly\_t* *poly*, *slong* *n*)

Sets *res* to *poly* divided by  $x^n$ , throwing away the lower coefficients. We require that *n* is nonnegative.

void **\_arb\_poly\_shift\_left**(*arb\_ptr* *res*, *arb\_srcptr* *poly*, *slong* *len*, *slong* *n*)

void **arb\_poly\_shift\_left**(*arb\_poly\_t* *res*, const *arb\_poly\_t* *poly*, *slong* *n*)

Sets *res* to *poly* multiplied by  $x^n$ . We require that *n* is nonnegative.

void **arb\_poly\_truncate**(*arb\_poly\_t* *poly*, *slong* *n*)

Truncates *poly* to have length at most *n*, i.e. degree strictly smaller than *n*. We require that *n* is nonnegative.

*slong* **arb\_poly\_valuation**(const *arb\_poly\_t* *poly*)

Returns the degree of the lowest term that is not exactly zero in *poly*. Returns -1 if *poly* is the zero polynomial.

### 5.1.4 Conversions

void **arb\_poly\_set\_fmpz\_poly**(*arb\_poly\_t poly*, const *fmpz\_poly\_t src*, *slong prec*)

void **arb\_poly\_set\_fmpq\_poly**(*arb\_poly\_t poly*, const *fmpq\_poly\_t src*, *slong prec*)

void **arb\_poly\_set\_si**(*arb\_poly\_t poly*, *slong src*)  
Sets *poly* to *src*, rounding the coefficients to *prec* bits.

### 5.1.5 Input and output

void **arb\_poly\_printd**(const *arb\_poly\_t poly*, *slong digits*)  
Prints the polynomial as an array of coefficients, printing each coefficient using *arb\_printd*.

void **arb\_poly\_fprintd**(FILE \* *file*, const *arb\_poly\_t poly*, *slong digits*)  
Prints the polynomial as an array of coefficients to the stream *file*, printing each coefficient using *arb\_fprintd*.

### 5.1.6 Random generation

void **arb\_poly\_randtest**(*arb\_poly\_t poly*, *flint\_rand\_t state*, *slong len*, *slong prec*,  
*slong mag\_bits*)  
Creates a random polynomial with length at most *len*.

### 5.1.7 Comparisons

int **arb\_poly\_contains**(const *arb\_poly\_t poly1*, const *arb\_poly\_t poly2*)

int **arb\_poly\_contains\_fmpz\_poly**(const *arb\_poly\_t poly1*, const *fmpz\_poly\_t poly2*)

int **arb\_poly\_contains\_fmpq\_poly**(const *arb\_poly\_t poly1*, const *fmpq\_poly\_t poly2*)  
Returns nonzero iff *poly1* contains *poly2*.

int **arb\_poly\_equal**(const *arb\_poly\_t A*, const *arb\_poly\_t B*)  
Returns nonzero iff *A* and *B* are equal as polynomial balls, i.e. all coefficients have equal midpoint and radius.

int **\_arb\_poly\_overlaps**(*arb\_srcptr poly1*, *slong len1*, *arb\_srcptr poly2*, *slong len2*)

int **arb\_poly\_overlaps**(const *arb\_poly\_t poly1*, const *arb\_poly\_t poly2*)  
Returns nonzero iff *poly1* overlaps with *poly2*. The underscore function requires that *len1* is at least as large as *len2*.

int **arb\_poly\_get\_unique\_fmpz\_poly**(*fmpz\_poly\_t z*, const *arb\_poly\_t x*)  
If *x* contains a unique integer polynomial, sets *z* to that value and returns nonzero. Otherwise (if *x* represents no integers or more than one integer), returns zero, possibly partially modifying *z*.

### 5.1.8 Bounds

void **\_arb\_poly\_majorant**(*arb\_ptr res*, *arb\_srcptr poly*, *slong len*, *slong prec*)

void **arb\_poly\_majorant**(*arb\_poly\_t res*, const *arb\_poly\_t poly*, *slong prec*)  
Sets *res* to an exact real polynomial whose coefficients are upper bounds for the absolute values of the coefficients in *poly*, rounded to *prec* bits.

### 5.1.9 Arithmetic

void `_arb_poly_add`(*arb\_ptr* C, *arb\_srcptr* A, *slong* lenA, *arb\_srcptr* B, *slong* lenB, *slong* prec)  
 Sets  $\{C, \max(\text{lenA}, \text{lenB})\}$  to the sum of  $\{A, \text{lenA}\}$  and  $\{B, \text{lenB}\}$ . Allows aliasing of the input and output operands.

void `arb_poly_add`(*arb\_poly\_t* C, const *arb\_poly\_t* A, const *arb\_poly\_t* B, *slong* prec)

void `arb_poly_add_si`(*arb\_poly\_t* C, const *arb\_poly\_t* A, *slong* B, *slong* prec)  
 Sets *C* to the sum of *A* and *B*.

void `_arb_poly_sub`(*arb\_ptr* C, *arb\_srcptr* A, *slong* lenA, *arb\_srcptr* B, *slong* lenB, *slong* prec)  
 Sets  $\{C, \max(\text{lenA}, \text{lenB})\}$  to the difference of  $\{A, \text{lenA}\}$  and  $\{B, \text{lenB}\}$ . Allows aliasing of the input and output operands.

void `arb_poly_sub`(*arb\_poly\_t* C, const *arb\_poly\_t* A, const *arb\_poly\_t* B, *slong* prec)  
 Sets *C* to the difference of *A* and *B*.

void `arb_poly_add_series`(*arb\_poly\_t* C, const *arb\_poly\_t* A, const *arb\_poly\_t* B, *slong* len, *slong* prec)  
 Sets *C* to the sum of *A* and *B*, truncated to length *len*.

void `arb_poly_sub_series`(*arb\_poly\_t* C, const *arb\_poly\_t* A, const *arb\_poly\_t* B, *slong* len, *slong* prec)  
 Sets *C* to the difference of *A* and *B*, truncated to length *len*.

void `arb_poly_neg`(*arb\_poly\_t* C, const *arb\_poly\_t* A)  
 Sets *C* to the negation of *A*.

void `arb_poly_scalar_mul_2exp_si`(*arb\_poly\_t* C, const *arb\_poly\_t* A, *slong* c)  
 Sets *C* to *A* multiplied by  $2^c$ .

void `arb_poly_scalar_mul`(*arb\_poly\_t* C, const *arb\_poly\_t* A, const *arb\_t* c, *slong* prec)  
 Sets *C* to *A* multiplied by *c*.

void `arb_poly_scalar_div`(*arb\_poly\_t* C, const *arb\_poly\_t* A, const *arb\_t* c, *slong* prec)  
 Sets *C* to *A* divided by *c*.

void `_arb_poly_mullo_classical`(*arb\_ptr* C, *arb\_srcptr* A, *slong* lenA, *arb\_srcptr* B, *slong* lenB, *slong* n, *slong* prec)

void `_arb_poly_mullo_block`(*arb\_ptr* C, *arb\_srcptr* A, *slong* lenA, *arb\_srcptr* B, *slong* lenB, *slong* n, *slong* prec)

void `_arb_poly_mullo`(*arb\_ptr* C, *arb\_srcptr* A, *slong* lenA, *arb\_srcptr* B, *slong* lenB, *slong* n, *slong* prec)  
 Sets  $\{C, n\}$  to the product of  $\{A, \text{lenA}\}$  and  $\{B, \text{lenB}\}$ , truncated to length *n*. The output is not allowed to be aliased with either of the inputs. We require  $\text{lenA} \geq \text{lenB} > 0$ ,  $n > 0$ ,  $\text{lenA} + \text{lenB} - 1 \geq n$ .

The *classical* version uses a plain loop. This has good numerical stability but gets slow for large *n*.

The *block* version decomposes the product into several subproducts which are computed exactly over the integers.

It first attempts to find an integer *c* such that  $A(2^c x)$  and  $B(2^c x)$  have slowly varying coefficients, to reduce the number of blocks.

The scaling factor *c* is chosen in a quick, heuristic way by picking the first and last nonzero terms in each polynomial. If the indices in *A* are  $a_2, a_1$  and the log-2 magnitudes are  $e_2, e_1$ , and the indices in *B* are  $b_2, b_1$  with corresponding magnitudes  $f_2, f_1$ , then we compute *c* as the weighted arithmetic mean of the slopes, rounded to the nearest integer:

$$c = \left\lfloor \frac{(e_2 - e_1) + (f_2 + f_1)}{(a_2 - a_1) + (b_2 - b_1)} + \frac{1}{2} \right\rfloor.$$

This strategy is used because it is simple. It is not optimal in all cases, but will typically give good performance when multiplying two power series with a similar decay rate.

The default algorithm chooses the *classical* algorithm for short polynomials and the *block* algorithm for long polynomials.

If the input pointers are identical (and the lengths are the same), they are assumed to represent the same polynomial, and its square is computed.

```
void arb_poly_mullo_classical(arb_poly_t C, const arb_poly_t A, const arb_poly_t B,
                             slong n, slong prec)
```

```
void arb_poly_mullo_ztrunc(arb_poly_t C, const arb_poly_t A, const arb_poly_t B, slong n,
                           slong prec)
```

```
void arb_poly_mullo_block(arb_poly_t C, const arb_poly_t A, const arb_poly_t B, slong n,
                          slong prec)
```

```
void arb_poly_mullo(arb_poly_t C, const arb_poly_t A, const arb_poly_t B, slong n,
                    slong prec)
```

Sets  $C$  to the product of  $A$  and  $B$ , truncated to length  $n$ . If the same variable is passed for  $A$  and  $B$ , sets  $C$  to the square of  $A$  truncated to length  $n$ .

```
void _arb_poly_mul(arb_ptr C, arb_srcptr A, slong lenA, arb_srcptr B, slong lenB, slong prec)
```

Sets  $\{C, lenA + lenB - 1\}$  to the product of  $\{A, lenA\}$  and  $\{B, lenB\}$ . The output is not allowed to be aliased with either of the inputs. We require  $lenA \geq lenB > 0$ . This function is implemented as a simple wrapper for `_arb_poly_mullo()`.

If the input pointers are identical (and the lengths are the same), they are assumed to represent the same polynomial, and its square is computed.

```
void arb_poly_mul(arb_poly_t C, const arb_poly_t A, const arb_poly_t B, slong prec)
```

Sets  $C$  to the product of  $A$  and  $B$ . If the same variable is passed for  $A$  and  $B$ , sets  $C$  to the square of  $A$ .

```
void _arb_poly_inv_series(arb_ptr Q, arb_srcptr A, slong Alen, slong len, slong prec)
```

Sets  $\{Q, len\}$  to the power series inverse of  $\{A, Alen\}$ . Uses Newton iteration.

```
void arb_poly_inv_series(arb_poly_t Q, const arb_poly_t A, slong n, slong prec)
```

Sets  $Q$  to the power series inverse of  $A$ , truncated to length  $n$ .

```
void _arb_poly_div_series(arb_ptr Q, arb_srcptr A, slong Alen, arb_srcptr B, slong Blen,
                          slong n, slong prec)
```

Sets  $\{Q, n\}$  to the power series quotient of  $\{A, Alen\}$  by  $\{B, Blen\}$ . Uses Newton iteration followed by multiplication.

```
void arb_poly_div_series(arb_poly_t Q, const arb_poly_t A, const arb_poly_t B, slong n,
                        slong prec)
```

Sets  $Q$  to the power series quotient  $A$  divided by  $B$ , truncated to length  $n$ .

```
void _arb_poly_div(arb_ptr Q, arb_srcptr A, slong lenA, arb_srcptr B, slong lenB, slong prec)
```

```
void _arb_poly_rem(arb_ptr R, arb_srcptr A, slong lenA, arb_srcptr B, slong lenB, slong prec)
```

```
void _arb_poly_divrem(arb_ptr Q, arb_ptr R, arb_srcptr A, slong lenA, arb_srcptr B,
                     slong lenB, slong prec)
```

```
int arb_poly_divrem(arb_poly_t Q, arb_poly_t R, const arb_poly_t A, const arb_poly_t B,
                   slong prec)
```

Performs polynomial division with remainder, computing a quotient  $Q$  and a remainder  $R$  such that  $A = BQ + R$ . The implementation reverses the inputs and performs power series division.

If the leading coefficient of  $B$  contains zero (or if  $B$  is identically zero), returns 0 indicating failure without modifying the outputs. Otherwise returns nonzero.

```
void _arb_poly_div_root(arb_ptr Q, arb_t R, arb_srcptr A, slong len, const arb_t c,
                       slong prec)
```

Divides  $A$  by the polynomial  $x - c$ , computing the quotient  $Q$  as well as the remainder  $R = f(c)$ .

### 5.1.10 Composition

```
void _arb_poly_taylor_shift_horner(arb_ptr g, const arb_t c, slong n, slong prec)
```

```
void arb_poly_taylor_shift_horner(arb_poly_t g, const arb_poly_t f, const arb_t c,
                                  slong prec)
```

```
void _arb_poly_taylor_shift_divconquer(arb_ptr g, const arb_t c, slong n, slong prec)
```

```
void arb_poly_taylor_shift_divconquer(arb_poly_t g, const arb_poly_t f, const arb_t c,
                                       slong prec)
```

```
void _arb_poly_taylor_shift_convolution(arb_ptr g, const arb_t c, slong n, slong prec)
```

```
void arb_poly_taylor_shift_convolution(arb_poly_t g, const arb_poly_t f, const arb_t c,
                                       slong prec)
```

```
void _arb_poly_taylor_shift(arb_ptr g, const arb_t c, slong n, slong prec)
```

```
void arb_poly_taylor_shift(arb_poly_t g, const arb_poly_t f, const arb_t c, slong prec)
```

Sets  $g$  to the Taylor shift  $f(x+c)$ , computed respectively using an optimized form of Horner's rule, divide-and-conquer, a single convolution, and an automatic choice between the three algorithms.

The underscore methods act in-place on  $g = f$  which has length  $n$ .

```
void _arb_poly_compose_horner(arb_ptr res, arb_srcptr poly1, slong len1, arb_srcptr poly2,
                              slong len2, slong prec)
```

```
void arb_poly_compose_horner(arb_poly_t res, const arb_poly_t poly1, const arb_poly_t poly2,
                              slong prec)
```

```
void _arb_poly_compose_divconquer(arb_ptr res, arb_srcptr poly1, slong len1,
                                   arb_srcptr poly2, slong len2, slong prec)
```

```
void arb_poly_compose_divconquer(arb_poly_t res, const arb_poly_t poly1, const
                                   arb_poly_t poly2, slong prec)
```

```
void _arb_poly_compose(arb_ptr res, arb_srcptr poly1, slong len1, arb_srcptr poly2, slong len2,
                        slong prec)
```

```
void arb_poly_compose(arb_poly_t res, const arb_poly_t poly1, const arb_poly_t poly2,
                        slong prec)
```

Sets  $res$  to the composition  $h(x) = f(g(x))$  where  $f$  is given by  $poly1$  and  $g$  is given by  $poly2$ , respectively using Horner's rule, divide-and-conquer, and an automatic choice between the two algorithms.

The default algorithm also handles special-form input  $g = ax^n + c$  efficiently by performing a Taylor shift followed by a rescaling.

The underscore methods do not support aliasing of the output with either input polynomial.

```
void _arb_poly_compose_series_horner(arb_ptr res, arb_srcptr poly1, slong len1,
                                      arb_srcptr poly2, slong len2, slong n, slong prec)
```

```
void arb_poly_compose_series_horner(arb_poly_t res, const arb_poly_t poly1, const
                                      arb_poly_t poly2, slong n, slong prec)
```

```
void _arb_poly_compose_series_brent_kung(arb_ptr res, arb_srcptr poly1, slong len1,
                                           arb_srcptr poly2, slong len2, slong n, slong prec)
```

```
void arb_poly_compose_series_brent_kung(arb_poly_t res, const arb_poly_t poly1, const
                                           arb_poly_t poly2, slong n, slong prec)
```

```
void _arb_poly_compose_series(arb_ptr res, arb_srcptr poly1, slong len1, arb_srcptr poly2,
                               slong len2, slong n, slong prec)
```

```
void arb_poly_compose_series(arb_poly_t res, const arb_poly_t poly1, const arb_poly_t poly2,
                               slong n, slong prec)
```

Sets  $res$  to the power series composition  $h(x) = f(g(x))$  truncated to order  $O(x^n)$  where  $f$  is given by  $poly1$  and  $g$  is given by  $poly2$ , respectively using Horner's rule, the Brent-Kung baby step-giant step algorithm, and an automatic choice between the two algorithms.

The default algorithm also handles special-form input  $g = ax^n$  efficiently.

We require that the constant term in  $g(x)$  is exactly zero. The underscore methods do not support aliasing of the output with either input polynomial.

```
void _arb_poly_revert_series_lagrange(arb_ptr h, arb_srcptr f, slong flen, slong n,
                                     slong prec)
```

```
void arb_poly_revert_series_lagrange(arb_poly_t h, const arb_poly_t f, slong n, slong prec)
```

```
void _arb_poly_revert_series_newton(arb_ptr h, arb_srcptr f, slong flen, slong n, slong prec)
```

```
void arb_poly_revert_series_newton(arb_poly_t h, const arb_poly_t f, slong n, slong prec)
```

```
void _arb_poly_revert_series_lagrange_fast(arb_ptr h, arb_srcptr f, slong flen, slong n,
                                           slong prec)
```

```
void arb_poly_revert_series_lagrange_fast(arb_poly_t h, const arb_poly_t f, slong n,
                                           slong prec)
```

```
void _arb_poly_revert_series(arb_ptr h, arb_srcptr f, slong flen, slong n, slong prec)
```

```
void arb_poly_revert_series(arb_poly_t h, const arb_poly_t f, slong n, slong prec)
```

Sets  $h$  to the power series reversion of  $f$ , i.e. the expansion of the compositional inverse function  $f^{-1}(x)$ , truncated to order  $O(x^n)$ , using respectively Lagrange inversion, Newton iteration, fast Lagrange inversion, and a default algorithm choice.

We require that the constant term in  $f$  is exactly zero and that the linear term is nonzero. The underscore methods assume that  $flen$  is at least 2, and do not support aliasing.

### 5.1.11 Evaluation

```
void _arb_poly_evaluate_horner(arb_t y, arb_srcptr f, slong len, const arb_t x, slong prec)
```

```
void arb_poly_evaluate_horner(arb_t y, const arb_poly_t f, const arb_t x, slong prec)
```

```
void _arb_poly_evaluate_rectangular(arb_t y, arb_srcptr f, slong len, const arb_t x,
                                     slong prec)
```

```
void arb_poly_evaluate_rectangular(arb_t y, const arb_poly_t f, const arb_t x, slong prec)
```

```
void _arb_poly_evaluate(arb_t y, arb_srcptr f, slong len, const arb_t x, slong prec)
```

```
void arb_poly_evaluate(arb_t y, const arb_poly_t f, const arb_t x, slong prec)
```

Sets  $y = f(x)$ , evaluated respectively using Horner's rule, rectangular splitting, and an automatic algorithm choice.

```
void _arb_poly_evaluate_acb_horner(acb_t y, arb_srcptr f, slong len, const acb_t x,
                                   slong prec)
```

```
void arb_poly_evaluate_acb_horner(acb_t y, const arb_poly_t f, const acb_t x, slong prec)
```

```
void _arb_poly_evaluate_acb_rectangular(acb_t y, arb_srcptr f, slong len, const acb_t x,
                                         slong prec)
```

```
void arb_poly_evaluate_acb_rectangular(acb_t y, const arb_poly_t f, const acb_t x,
                                         slong prec)
```

```
void _arb_poly_evaluate_acb(acb_t y, arb_srcptr f, slong len, const acb_t x, slong prec)
```

```
void arb_poly_evaluate_acb(acb_t y, const arb_poly_t f, const acb_t x, slong prec)
```

Sets  $y = f(x)$  where  $x$  is a complex number, evaluating the polynomial respectively using Horner's rule, rectangular splitting, and an automatic algorithm choice.

```
void _arb_poly_evaluate2_horner(arb_t y, arb_t z, arb_srcptr f, slong len, const arb_t x,
                                slong prec)
```

```
void arb_poly_evaluate2_horner(arb_t y, arb_t z, const arb_poly_t f, const arb_t x,
                                slong prec)
```

```
void _arb_poly_evaluate2_rectangular(arb_t y, arb_t z, arb_srcptr f, slong len, const arb_t x,
                                     slong prec)
```

```
void arb_poly_evaluate2_rectangular(arb_t y, arb_t z, const arb_poly_t f, const arb_t x,
                                    slong prec)
```

```
void _arb_poly_evaluate2(arb_t y, arb_t z, arb_srcptr f, slong len, const arb_t x, slong prec)
```

```
void arb_poly_evaluate2(arb_t y, arb_t z, const arb_poly_t f, const arb_t x, slong prec)
```

Sets  $y = f(x)$ ,  $z = f'(x)$ , evaluated respectively using Horner's rule, rectangular splitting, and an automatic algorithm choice.

When Horner's rule is used, the only advantage of evaluating the function and its derivative simultaneously is that one does not have to generate the derivative polynomial explicitly. With the rectangular splitting algorithm, the powers can be reused, making simultaneous evaluation slightly faster.

```
void _arb_poly_evaluate2_acb_horner(acb_t y, acb_t z, arb_srcptr f, slong len, const acb_t x,
                                    slong prec)
```

```
void arb_poly_evaluate2_acb_horner(acb_t y, acb_t z, const arb_poly_t f, const acb_t x,
                                    slong prec)
```

```
void _arb_poly_evaluate2_acb_rectangular(acb_t y, acb_t z, arb_srcptr f, slong len, const
                                         acb_t x, slong prec)
```

```
void arb_poly_evaluate2_acb_rectangular(acb_t y, acb_t z, const arb_poly_t f, const
                                         acb_t x, slong prec)
```

```
void _arb_poly_evaluate2_acb(acb_t y, acb_t z, arb_srcptr f, slong len, const acb_t x,
                             slong prec)
```

```
void arb_poly_evaluate2_acb(acb_t y, acb_t z, const arb_poly_t f, const acb_t x, slong prec)
```

Sets  $y = f(x)$ ,  $z = f'(x)$ , evaluated respectively using Horner's rule, rectangular splitting, and an automatic algorithm choice.

## 5.1.12 Product trees

```
void _arb_poly_product_roots(arb_ptr poly, arb_srcptr xs, slong n, slong prec)
```

```
void arb_poly_product_roots(arb_poly_t poly, arb_srcptr xs, slong n, slong prec)
```

Generates the polynomial  $(x - x_0)(x - x_1) \cdots (x - x_{n-1})$ .

```
void _arb_poly_product_roots_complex(arb_ptr poly, arb_srcptr r, slong rn, acb_srcptr c,
                                     slong cn, slong prec)
```

```
void arb_poly_product_roots_complex(arb_poly_t poly, arb_srcptr r, slong rn, acb_srcptr c,
                                    slong cn, slong prec)
```

Generates the polynomial

$$\left( \prod_{i=0}^{rn-1} (x - r_i) \right) \left( \prod_{i=0}^{cn-1} (x - c_i)(x - \bar{c}_i) \right)$$

having  $rn$  real roots given by the array  $r$  and having  $2cn$  complex roots in conjugate pairs given by the length- $cn$  array  $c$ . Either  $rn$  or  $cn$  or both may be zero.

Note that only one representative from each complex conjugate pair is supplied (unless a pair is supposed to be repeated with higher multiplicity). To construct a polynomial from complex roots where the conjugate pairs have not been distinguished, use `acb_poly_product_roots()` instead.

```
arb_ptr * _arb_poly_tree_alloc(slong len)
```

Returns an initialized data structured capable of representing a remainder tree (product tree) of  $len$  roots.

```
void _arb_poly_tree_free(arb_ptr * tree, slong len)
```

Deallocates a tree structure as allocated using `_arb_poly_tree_alloc`.

void `_arb_poly_tree_build`(*arb\_ptr* \* *tree*, *arb\_srcptr* *roots*, *slong* *len*, *slong* *prec*)  
 Constructs a product tree from a given array of *len* roots. The tree structure must be pre-allocated to the specified length using `_arb_poly_tree_alloc()`.

### 5.1.13 Multipoint evaluation

void `_arb_poly_evaluate_vec_iter`(*arb\_ptr* *ys*, *arb\_srcptr* *poly*, *slong* *plen*, *arb\_srcptr* *xs*, *slong* *n*, *slong* *prec*)  
 void `arb_poly_evaluate_vec_iter`(*arb\_ptr* *ys*, const *arb\_poly\_t* *poly*, *arb\_srcptr* *xs*, *slong* *n*, *slong* *prec*)  
 Evaluates the polynomial simultaneously at *n* given points, calling `_arb_poly_evaluate()` repeatedly.  
 void `_arb_poly_evaluate_vec_fast_precomp`(*arb\_ptr* *ys*, *arb\_srcptr* *poly*, *slong* *plen*, *arb\_ptr* \* *tree*, *slong* *len*, *slong* *prec*)  
 void `_arb_poly_evaluate_vec_fast`(*arb\_ptr* *ys*, *arb\_srcptr* *poly*, *slong* *plen*, *arb\_srcptr* *xs*, *slong* *n*, *slong* *prec*)  
 void `arb_poly_evaluate_vec_fast`(*arb\_ptr* *ys*, const *arb\_poly\_t* *poly*, *arb\_srcptr* *xs*, *slong* *n*, *slong* *prec*)  
 Evaluates the polynomial simultaneously at *n* given points, using fast multipoint evaluation.

### 5.1.14 Interpolation

void `_arb_poly_interpolate_newton`(*arb\_ptr* *poly*, *arb\_srcptr* *xs*, *arb\_srcptr* *ys*, *slong* *n*, *slong* *prec*)  
 void `arb_poly_interpolate_newton`(*arb\_poly\_t* *poly*, *arb\_srcptr* *xs*, *arb\_srcptr* *ys*, *slong* *n*, *slong* *prec*)  
 Recovers the unique polynomial of length at most *n* that interpolates the given *x* and *y* values. This implementation first interpolates in the Newton basis and then converts back to the monomial basis.  
 void `_arb_poly_interpolate_barycentric`(*arb\_ptr* *poly*, *arb\_srcptr* *xs*, *arb\_srcptr* *ys*, *slong* *n*, *slong* *prec*)  
 void `arb_poly_interpolate_barycentric`(*arb\_poly\_t* *poly*, *arb\_srcptr* *xs*, *arb\_srcptr* *ys*, *slong* *n*, *slong* *prec*)  
 Recovers the unique polynomial of length at most *n* that interpolates the given *x* and *y* values. This implementation uses the barycentric form of Lagrange interpolation.  
 void `_arb_poly_interpolation_weights`(*arb\_ptr* *w*, *arb\_ptr* \* *tree*, *slong* *len*, *slong* *prec*)  
 void `_arb_poly_interpolate_fast_precomp`(*arb\_ptr* *poly*, *arb\_srcptr* *ys*, *arb\_ptr* \* *tree*, *arb\_srcptr* *weights*, *slong* *len*, *slong* *prec*)  
 void `_arb_poly_interpolate_fast`(*arb\_ptr* *poly*, *arb\_srcptr* *xs*, *arb\_srcptr* *ys*, *slong* *len*, *slong* *prec*)  
 void `arb_poly_interpolate_fast`(*arb\_poly\_t* *poly*, *arb\_srcptr* *xs*, *arb\_srcptr* *ys*, *slong* *n*, *slong* *prec*)  
 Recovers the unique polynomial of length at most *n* that interpolates the given *x* and *y* values, using fast Lagrange interpolation. The precomp function takes a precomputed product tree over the *x* values and a vector of interpolation weights as additional inputs.

### 5.1.15 Differentiation

void `_arb_poly_derivative`(*arb\_ptr* *res*, *arb\_srcptr* *poly*, *slong* *len*, *slong* *prec*)  
 Sets  $\{res, len - 1\}$  to the derivative of  $\{poly, len\}$ . Allows aliasing of the input and output.  
 void `arb_poly_derivative`(*arb\_poly\_t* *res*, const *arb\_poly\_t* *poly*, *slong* *prec*)  
 Sets *res* to the derivative of *poly*.

void `_arb_poly_integral`(*arb\_ptr* res, *arb\_srcptr* poly, *slong* len, *slong* prec)  
Sets  $\{res, len\}$  to the integral of  $\{poly, len - 1\}$ . Allows aliasing of the input and output.

void `arb_poly_integral`(*arb\_poly\_t* res, const *arb\_poly\_t* poly, *slong* prec)  
Sets *res* to the integral of *poly*.

### 5.1.16 Transforms

void `_arb_poly_borel_transform`(*arb\_ptr* res, *arb\_srcptr* poly, *slong* len, *slong* prec)

void `arb_poly_borel_transform`(*arb\_poly\_t* res, const *arb\_poly\_t* poly, *slong* prec)  
Computes the Borel transform of the input polynomial, mapping  $\sum_k a_k x^k$  to  $\sum_k (a_k/k!)x^k$ . The underscore method allows aliasing.

void `_arb_poly_inv_borel_transform`(*arb\_ptr* res, *arb\_srcptr* poly, *slong* len, *slong* prec)

void `arb_poly_inv_borel_transform`(*arb\_poly\_t* res, const *arb\_poly\_t* poly, *slong* prec)  
Computes the inverse Borel transform of the input polynomial, mapping  $\sum_k a_k x^k$  to  $\sum_k a_k k! x^k$ . The underscore method allows aliasing.

void `_arb_poly_binomial_transform_basecase`(*arb\_ptr* b, *arb\_srcptr* a, *slong* alen, *slong* len, *slong* prec)

void `arb_poly_binomial_transform_basecase`(*arb\_poly\_t* b, const *arb\_poly\_t* a, *slong* len, *slong* prec)

void `_arb_poly_binomial_transform_convolution`(*arb\_ptr* b, *arb\_srcptr* a, *slong* alen, *slong* len, *slong* prec)

void `arb_poly_binomial_transform_convolution`(*arb\_poly\_t* b, const *arb\_poly\_t* a, *slong* len, *slong* prec)

void `_arb_poly_binomial_transform`(*arb\_ptr* b, *arb\_srcptr* a, *slong* alen, *slong* len, *slong* prec)

void `arb_poly_binomial_transform`(*arb\_poly\_t* b, const *arb\_poly\_t* a, *slong* len, *slong* prec)  
Computes the binomial transform of the input polynomial, truncating the output to length *len*. The binomial transform maps the coefficients  $a_k$  in the input polynomial to the coefficients  $b_k$  in the output polynomial via  $b_n = \sum_{k=0}^n (-1)^k \binom{n}{k} a_k$ . The binomial transform is equivalent to the power series composition  $f(x) \rightarrow (1-x)^{-1} f(x/(x-1))$ , and is its own inverse.

The *basecase* version evaluates coefficients one by one from the definition, generating the binomial coefficients by a recurrence relation.

The *convolution* version uses the identity  $T(f(x)) = B^{-1}(e^x B(f(-x)))$  where  $T$  denotes the binomial transform operator and  $B$  denotes the Borel transform operator. This only costs a single polynomial multiplication, plus some scalar operations.

The default version automatically chooses an algorithm.

The underscore methods do not support aliasing, and assume that the lengths are nonzero.

### 5.1.17 Powers and elementary functions

void `_arb_poly_pow_ui_trunc_binexp`(*arb\_ptr* res, *arb\_srcptr* f, *slong* flen, *ulong* exp, *slong* len, *slong* prec)

Sets  $\{res, len\}$  to  $\{f, flen\}$  raised to the power *exp*, truncated to length *len*. Requires that *len* is no longer than the length of the power as computed without truncation (i.e. no zero-padding is performed). Does not support aliasing of the input and output, and requires that *flen* and *len* are positive. Uses binary exponentiation.

void `arb_poly_pow_ui_trunc_binexp`(*arb\_poly\_t* res, const *arb\_poly\_t* poly, *ulong* exp, *slong* len, *slong* prec)

Sets *res* to *poly* raised to the power *exp*, truncated to length *len*. Uses binary exponentiation.

---

```
void _arb_poly_pow_ui(arb_ptr res, arb_srcptr f, slong flen, ulong exp, slong prec)
```

Sets *res* to  $\{f, flen\}$  raised to the power *exp*. Does not support aliasing of the input and output, and requires that *flen* is positive.

```
void arb_poly_pow_ui(arb_poly_t res, const arb_poly_t poly, ulong exp, slong prec)
```

Sets *res* to *poly* raised to the power *exp*.

```
void _arb_poly_pow_series(arb_ptr h, arb_srcptr f, slong flen, arb_srcptr g, slong glen,
                        slong len, slong prec)
```

Sets  $\{h, len\}$  to the power series  $f(x)^{g(x)} = \exp(g(x) \log f(x))$  truncated to length *len*. This function detects special cases such as *g* being an exact small integer or  $\pm 1/2$ , and computes such powers more efficiently. This function does not support aliasing of the output with either of the input operands. It requires that all lengths are positive, and assumes that *flen* and *glen* do not exceed *len*.

```
void arb_poly_pow_series(arb_poly_t h, const arb_poly_t f, const arb_poly_t g, slong len,
                        slong prec)
```

Sets *h* to the power series  $f(x)^{g(x)} = \exp(g(x) \log f(x))$  truncated to length *len*. This function detects special cases such as *g* being an exact small integer or  $\pm 1/2$ , and computes such powers more efficiently.

```
void _arb_poly_pow_arb_series(arb_ptr h, arb_srcptr f, slong flen, const arb_t g, slong len,
                            slong prec)
```

Sets  $\{h, len\}$  to the power series  $f(x)^g = \exp(g \log f(x))$  truncated to length *len*. This function detects special cases such as *g* being an exact small integer or  $\pm 1/2$ , and computes such powers more efficiently. This function does not support aliasing of the output with either of the input operands. It requires that all lengths are positive, and assumes that *flen* does not exceed *len*.

```
void arb_poly_pow_arb_series(arb_poly_t h, const arb_poly_t f, const arb_t g, slong len,
                            slong prec)
```

Sets *h* to the power series  $f(x)^g = \exp(g \log f(x))$  truncated to length *len*.

```
void _arb_poly_sqrt_series(arb_ptr g, arb_srcptr h, slong hlen, slong n, slong prec)
```

```
void arb_poly_sqrt_series(arb_poly_t g, const arb_poly_t h, slong n, slong prec)
```

Sets *g* to the power series square root of *h*, truncated to length *n*. Uses division-free Newton iteration for the reciprocal square root, followed by a multiplication.

The underscore method does not support aliasing of the input and output arrays. It requires that *hlen* and *n* are greater than zero.

```
void _arb_poly_rsqrt_series(arb_ptr g, arb_srcptr h, slong hlen, slong n, slong prec)
```

```
void arb_poly_rsqrt_series(arb_poly_t g, const arb_poly_t h, slong n, slong prec)
```

Sets *g* to the reciprocal power series square root of *h*, truncated to length *n*. Uses division-free Newton iteration.

The underscore method does not support aliasing of the input and output arrays. It requires that *hlen* and *n* are greater than zero.

```
void _arb_poly_log_series(arb_ptr res, arb_srcptr f, slong flen, slong n, slong prec)
```

```
void arb_poly_log_series(arb_poly_t res, const arb_poly_t f, slong n, slong prec)
```

Sets *res* to the power series logarithm of *f*, truncated to length *n*. Uses the formula  $\log(f(x)) = \int f'(x)/f(x)dx$ , adding the logarithm of the constant term in *f* as the constant of integration.

The underscore method supports aliasing of the input and output arrays. It requires that *flen* and *n* are greater than zero.

```
void _arb_poly_log1p_series(arb_ptr res, arb_srcptr f, slong flen, slong n, slong prec)
```

```
void arb_poly_log1p_series(arb_poly_t res, const arb_poly_t f, slong n, slong prec)
```

Computes the power series  $\log(1 + f)$ , with better accuracy when the constant term of *f* is small.

```
void _arb_poly_atan_series(arb_ptr res, arb_srcptr f, slong flen, slong n, slong prec)
```

```
void arb_poly_atan_series(arb_poly_t res, const arb_poly_t f, slong n, slong prec)
```

```
void _arb_poly_asin_series(arb_ptr res, arb_srcptr f, slong flen, slong n, slong prec)
```

```
void arb_poly_asin_series(arb_poly_t res, const arb_poly_t f, slong n, slong prec)
```

```
void _arb_poly_acos_series(arb_ptr res, arb_srcptr f, slong flen, slong n, slong prec)
```

```
void arb_poly_acos_series(arb_poly_t res, const arb_poly_t f, slong n, slong prec)
```

Sets *res* respectively to the power series inverse tangent, inverse sine and inverse cosine of *f*, truncated to length *n*.

Uses the formulas

$$\begin{aligned}\tan^{-1}(f(x)) &= \int f'(x)/(1 + f(x)^2)dx, \\ \sin^{-1}(f(x)) &= \int f'(x)/(1 - f(x)^2)^{1/2}dx, \\ \cos^{-1}(f(x)) &= - \int f'(x)/(1 - f(x)^2)^{1/2}dx,\end{aligned}$$

adding the inverse function of the constant term in *f* as the constant of integration.

The underscore methods supports aliasing of the input and output arrays. They require that *flen* and *n* are greater than zero.

```
void _arb_poly_exp_series_basecase(arb_ptr f, arb_srcptr h, slong hlen, slong n, slong prec)
```

```
void arb_poly_exp_series_basecase(arb_poly_t f, const arb_poly_t h, slong n, slong prec)
```

```
void _arb_poly_exp_series(arb_ptr f, arb_srcptr h, slong hlen, slong n, slong prec)
```

```
void arb_poly_exp_series(arb_poly_t f, const arb_poly_t h, slong n, slong prec)
```

Sets *f* to the power series exponential of *h*, truncated to length *n*.

The basecase version uses a simple recurrence for the coefficients, requiring  $O(nm)$  operations where *m* is the length of *h*.

The main implementation uses Newton iteration, starting from a small number of terms given by the basecase algorithm. The complexity is  $O(M(n))$ . Redundant operations in the Newton iteration are avoided by using the scheme described in [HZ2004].

The underscore methods support aliasing and allow the input to be shorter than the output, but require the lengths to be nonzero.

```
void _arb_poly_sin_cos_series_basecase(arb_ptr s, arb_ptr c, arb_srcptr h, slong hlen,
                                       slong n, slong prec, int times_pi)
```

```
void arb_poly_sin_cos_series_basecase(arb_poly_t s, arb_poly_t c, const arb_poly_t h,
                                       slong n, slong prec, int times_pi)
```

```
void _arb_poly_sin_cos_series_tangent(arb_ptr s, arb_ptr c, arb_srcptr h, slong hlen,
                                       slong n, slong prec, int times_pi)
```

```
void arb_poly_sin_cos_series_tangent(arb_poly_t s, arb_poly_t c, const arb_poly_t h,
                                       slong n, slong prec, int times_pi)
```

```
void _arb_poly_sin_cos_series(arb_ptr s, arb_ptr c, arb_srcptr h, slong hlen, slong n,
                              slong prec)
```

```
void arb_poly_sin_cos_series(arb_poly_t s, arb_poly_t c, const arb_poly_t h, slong n,
                              slong prec)
```

Sets *s* and *c* to the power series sine and cosine of *h*, computed simultaneously.

The *basecase* version uses a simple recurrence for the coefficients, requiring  $O(nm)$  operations where *m* is the length of *h*.

The *tangent* version uses the tangent half-angle formulas to compute the sine and cosine via `_arb_poly_tan_series()`. This requires  $O(M(n))$  operations. When  $h = h_0 + h_1$  where the constant term  $h_0$  is nonzero, the evaluation is done as  $\sin(h_0 + h_1) = \cos(h_0) \sin(h_1) + \sin(h_0) \cos(h_1)$ ,  $\cos(h_0 + h_1) = \cos(h_0) \cos(h_1) - \sin(h_0) \sin(h_1)$ , to improve accuracy and avoid dividing by zero at the poles of the tangent function.

The default version automatically selects between the *basecase* and *tangent* algorithms depending on the input.

The *basecase* and *tangent* versions take a flag *times\_pi* specifying that the input is to be multiplied by  $\pi$ .

The underscore methods support aliasing and require the lengths to be nonzero.

```
void _arb_poly_sin_series(arb_ptr s, arb_srcptr h, slong hlen, slong n, slong prec)
```

```
void arb_poly_sin_series(arb_poly_t s, const arb_poly_t h, slong n, slong prec)
```

```
void _arb_poly_cos_series(arb_ptr c, arb_srcptr h, slong hlen, slong n, slong prec)
```

```
void arb_poly_cos_series(arb_poly_t c, const arb_poly_t h, slong n, slong prec)
```

Respectively evaluates the power series sine or cosine. These functions simply wrap `_arb_poly_sin_cos_series()`. The underscore methods support aliasing and require the lengths to be nonzero.

```
void _arb_poly_tan_series(arb_ptr g, arb_srcptr h, slong hlen, slong len, slong prec)
```

```
void arb_poly_tan_series(arb_poly_t g, const arb_poly_t h, slong n, slong prec)
```

Sets *g* to the power series tangent of *h*.

For small *n* takes the quotient of the sine and cosine as computed using the basecase algorithm. For large *n*, uses Newton iteration to invert the inverse tangent series. The complexity is  $O(M(n))$ .

The underscore version does not support aliasing, and requires the lengths to be nonzero.

```
void _arb_poly_sin_cos_pi_series(arb_ptr s, arb_ptr c, arb_srcptr h, slong hlen, slong n,
                                slong prec)
```

```
void arb_poly_sin_cos_pi_series(arb_poly_t s, arb_poly_t c, const arb_poly_t h, slong n,
                                slong prec)
```

```
void _arb_poly_sin_pi_series(arb_ptr s, arb_srcptr h, slong hlen, slong n, slong prec)
```

```
void arb_poly_sin_pi_series(arb_poly_t s, const arb_poly_t h, slong n, slong prec)
```

```
void _arb_poly_cos_pi_series(arb_ptr c, arb_srcptr h, slong hlen, slong n, slong prec)
```

```
void arb_poly_cos_pi_series(arb_poly_t c, const arb_poly_t h, slong n, slong prec)
```

```
void _arb_poly_cot_pi_series(arb_ptr c, arb_srcptr h, slong hlen, slong n, slong prec)
```

```
void arb_poly_cot_pi_series(arb_poly_t c, const arb_poly_t h, slong n, slong prec)
```

Compute the respective trigonometric functions of the input multiplied by  $\pi$ .

```
void _arb_poly_sinh_cosh_series_basecase(arb_ptr s, arb_ptr c, arb_srcptr h, slong hlen,
                                          slong n, slong prec)
```

```
void arb_poly_sinh_cosh_series_basecase(arb_poly_t s, arb_poly_t c, const arb_poly_t h,
                                          slong n, slong prec)
```

```
void _arb_poly_sinh_cosh_series_exponential(arb_ptr s, arb_ptr c, arb_srcptr h, slong hlen,
                                             slong n, slong prec)
```

```
void arb_poly_sinh_cosh_series_exponential(arb_poly_t s, arb_poly_t c, const
                                             arb_poly_t h, slong n, slong prec)
```

```
void _arb_poly_sinh_cosh_series(arb_ptr s, arb_ptr c, arb_srcptr h, slong hlen, slong n,
                                slong prec)
```

```
void arb_poly_sinh_cosh_series(arb_poly_t s, arb_poly_t c, const arb_poly_t h, slong n,
                                slong prec)
```

```
void _arb_poly_sinh_series(arb_ptr s, arb_srcptr h, slong hlen, slong n, slong prec)
```

```
void arb_poly_sinh_series(arb_poly_t s, const arb_poly_t h, slong n, slong prec)
```

```
void _arb_poly_cosh_series(arb_ptr c, arb_srcptr h, slong hlen, slong n, slong prec)
```

void **arb\_poly\_cosh\_series**(*arb\_poly\_t* c, const *arb\_poly\_t* h, *slong* n, *slong* prec)  
Sets *s* and *c* respectively to the hyperbolic sine and cosine of the power series *h*, truncated to length *n*.

The implementations mirror those for sine and cosine, except that the *exponential* version computes both functions using the exponential function instead of the hyperbolic tangent.

void **\_arb\_poly\_sinc\_series**(*arb\_ptr* s, *arb\_srcptr* h, *slong* hlen, *slong* n, *slong* prec)

void **arb\_poly\_sinc\_series**(*arb\_poly\_t* s, const *arb\_poly\_t* h, *slong* n, *slong* prec)  
Sets *c* to the sinc function of the power series *h*, truncated to length *n*.

### 5.1.18 Lambert W function

void **\_arb\_poly\_lambertw\_series**(*arb\_ptr* res, *arb\_srcptr* z, *slong* zlen, int flags, *slong* len, *slong* prec)

void **arb\_poly\_lambertw\_series**(*arb\_poly\_t* res, const *arb\_poly\_t* z, int flags, *slong* len, *slong* prec)

Sets *res* to the Lambert W function of the power series *z*. If *flags* is 0, the principal branch is computed; if *flags* is 1, the second real branch  $W_{-1}(z)$  is computed. The underscore method allows aliasing, but assumes that the lengths are nonzero.

### 5.1.19 Gamma function and factorials

void **\_arb\_poly\_gamma\_series**(*arb\_ptr* res, *arb\_srcptr* h, *slong* hlen, *slong* n, *slong* prec)

void **arb\_poly\_gamma\_series**(*arb\_poly\_t* res, const *arb\_poly\_t* h, *slong* n, *slong* prec)

void **\_arb\_poly\_rgamma\_series**(*arb\_ptr* res, *arb\_srcptr* h, *slong* hlen, *slong* n, *slong* prec)

void **arb\_poly\_rgamma\_series**(*arb\_poly\_t* res, const *arb\_poly\_t* h, *slong* n, *slong* prec)

void **\_arb\_poly\_lgamma\_series**(*arb\_ptr* res, *arb\_srcptr* h, *slong* hlen, *slong* n, *slong* prec)

void **arb\_poly\_lgamma\_series**(*arb\_poly\_t* res, const *arb\_poly\_t* h, *slong* n, *slong* prec)

void **\_arb\_poly\_digamma\_series**(*arb\_ptr* res, *arb\_srcptr* h, *slong* hlen, *slong* n, *slong* prec)

void **arb\_poly\_digamma\_series**(*arb\_poly\_t* res, const *arb\_poly\_t* h, *slong* n, *slong* prec)  
Sets *res* to the series expansion of  $\Gamma(h(x))$ ,  $1/\Gamma(h(x))$ , or  $\log \Gamma(h(x))$ ,  $\psi(h(x))$ , truncated to length *n*.

These functions first generate the Taylor series at the constant term of *h*, and then call **\_arb\_poly\_compose\_series()**. The Taylor coefficients are generated using the Riemann zeta function if the constant term of *h* is a small integer, and with Stirling's series otherwise.

The underscore methods support aliasing of the input and output arrays, and require that *hlen* and *n* are greater than zero.

void **\_arb\_poly\_rising\_ui\_series**(*arb\_ptr* res, *arb\_srcptr* f, *slong* flen, *ulong* r, *slong* trunc, *slong* prec)

void **arb\_poly\_rising\_ui\_series**(*arb\_poly\_t* res, const *arb\_poly\_t* f, *ulong* r, *slong* trunc, *slong* prec)

Sets *res* to the rising factorial  $(f)(f+1)(f+2)\cdots(f+r-1)$ , truncated to length *trunc*. The underscore method assumes that *flen*, *r* and *trunc* are at least 1, and does not support aliasing. Uses binary splitting.

### 5.1.20 Zeta function

void **arb\_poly\_zeta\_series**(*arb\_poly\_t* res, const *arb\_poly\_t* s, const *arb\_t* a, int deflate, *slong* n, *slong* prec)

Sets *res* to the Hurwitz zeta function  $\zeta(s, a)$  where *s* a power series and *a* is a constant, truncated

to length  $n$ . To evaluate the usual Riemann zeta function, set  $a = 1$ .

If *deflate* is nonzero, evaluates  $\zeta(s, a) + 1/(1-s)$ , which is well-defined as a limit when the constant term of  $s$  is 1. In particular, expanding  $\zeta(s, a) + 1/(1-s)$  with  $s = 1+x$  gives the Stieltjes constants

$$\sum_{k=0}^{n-1} \frac{(-1)^k}{k!} \gamma_k(a) x^k.$$

If  $a = 1$ , this implementation uses the reflection formula if the midpoint of the constant term of  $s$  is negative.

```
void _arb_poly_riemann_siegel_theta_series(arb_ptr res, arb_srcptr h, slong hlen, slong n,
                                           slong prec)
```

```
void arb_poly_riemann_siegel_theta_series(arb_poly_t res, const arb_poly_t h, slong n,
                                           slong prec)
```

Sets *res* to the series expansion of the Riemann-Siegel theta function

$$\theta(h) = \arg \left( \Gamma \left( \frac{2ih + 1}{4} \right) \right) - \frac{\log \pi}{2} h$$

where the argument of the gamma function is chosen continuously as the imaginary part of the log gamma function.

The underscore method does not support aliasing of the input and output arrays, and requires that the lengths are greater than zero.

```
void _arb_poly_riemann_siegel_z_series(arb_ptr res, arb_srcptr h, slong hlen, slong n,
                                       slong prec)
```

```
void arb_poly_riemann_siegel_z_series(arb_poly_t res, const arb_poly_t h, slong n,
                                       slong prec)
```

Sets *res* to the series expansion of the Riemann-Siegel Z-function

$$Z(h) = e^{i\theta(h)} \zeta(1/2 + ih).$$

The zeros of the Z-function on the real line precisely correspond to the imaginary parts of the zeros of the Riemann zeta function on the critical line.

The underscore method supports aliasing of the input and output arrays, and requires that the lengths are greater than zero.

### 5.1.21 Root-finding

```
void _arb_poly_root_bound_fujiwara(mag_t bound, arb_srcptr poly, slong len)
```

```
void arb_poly_root_bound_fujiwara(mag_t bound, arb_poly_t poly)
```

Sets *bound* to an upper bound for the magnitude of all the complex roots of *poly*. Uses Fujiwara's bound

$$2 \max \left\{ \left| \frac{a_{n-1}}{a_n} \right|, \left| \frac{a_{n-2}}{a_n} \right|^{1/2}, \dots, \left| \frac{a_1}{a_n} \right|^{1/(n-1)}, \left| \frac{a_0}{2a_n} \right|^{1/n} \right\}$$

where  $a_0, \dots, a_n$  are the coefficients of *poly*.

```
void _arb_poly_newton_convergence_factor(arf_t convergence_factor, arb_srcptr poly,
                                         slong len, const arb_t convergence_interval,
                                         slong prec)
```

Given an interval  $I$  specified by *convergence\_interval*, evaluates a bound for  $C = \sup_{t,u \in I} \frac{1}{2} |f''(t)|/|f'(u)|$ , where  $f$  is the polynomial defined by the coefficients  $\{poly, len\}$ . The bound is obtained by evaluating  $f'(I)$  and  $f''(I)$  directly. If  $f$  has large coefficients,  $I$  must be extremely precise in order to get a finite factor.

```
int _arb_poly_newton_step(arb_t xnew, arb_srcptr poly, slong len, const arb_t x,
                        const arb_t convergence_interval, const arf_t convergence_factor,
                        slong prec)
```

Performs a single step with Newton's method.

The input consists of the polynomial  $f$  specified by the coefficients  $\{poly, len\}$ , an interval  $x = [m - r, m + r]$  known to contain a single root of  $f$ , an interval  $I$  ( $convergence\_interval$ ) containing  $x$  with an associated bound ( $convergence\_factor$ ) for  $C = \sup_{t,u \in I} \frac{1}{2} |f''(t)|/|f'(u)|$ , and a working precision  $prec$ .

The Newton update consists of setting  $x' = [m' - r', m' + r']$  where  $m' = m - f(m)/f'(m)$  and  $r' = Cr^2$ . The expression  $m - f(m)/f'(m)$  is evaluated using ball arithmetic at a working precision of  $prec$  bits, and the rounding error during this evaluation is accounted for in the output. We now check that  $x' \in I$  and  $m' < m$ . If both conditions are satisfied, we set  $xnew$  to  $x'$  and return nonzero. If either condition fails, we set  $xnew$  to  $x$  and return zero, indicating that no progress was made.

```
void _arb_poly_newton_refine_root(arb_t r, arb_srcptr poly, slong len, const arb_t start,
                                const arb_t convergence_interval, const arf_t convergence_factor, slong eval_extra_prec, slong prec)
```

Refines a precise estimate of a polynomial root to high precision by performing several Newton steps, using nearly optimally chosen doubling precision steps.

The inputs are defined as for `_arb_poly_newton_step`, except for the precision parameters:  $prec$  is the target accuracy and  $eval\_extra\_prec$  is the estimated number of guard bits that need to be added to evaluate the polynomial accurately close to the root (typically, if the polynomial has large coefficients of alternating signs, this needs to be approximately the bit size of the coefficients).

## 5.1.22 Other special polynomials

```
void _arb_poly_swinnerton_dyer_ui(arb_ptr poly, ulong n, slong trunc, slong prec)
```

```
void arb_poly_swinnerton_dyer_ui(arb_poly_t poly, ulong n, slong prec)
```

Computes the Swinnerton-Dyer polynomial  $S_n$ , which has degree  $2^n$  and is the rational minimal polynomial of the sum of the square roots of the first  $n$  prime numbers.

If  $prec$  is set to zero, a precision is chosen automatically such that `arb_poly_get_unique_fmpz_poly()` should be successful. Otherwise a working precision of  $prec$  bits is used.

The underscore version accepts an additional  $trunc$  parameter. Even when computing a truncated polynomial, the array  $poly$  must have room for  $2^n + 1$  coefficients, used as temporary space.

## 5.2 acb\_poly.h – polynomials over the complex numbers

An `acb_poly_t` represents a polynomial over the complex numbers, implemented as an array of coefficients of type `acb_struct`.

Most functions are provided in two versions: an underscore method which operates directly on pre-allocated arrays of coefficients and generally has some restrictions (such as requiring the lengths to be nonzero and not supporting aliasing of the input and output arrays), and a non-underscore method which performs automatic memory management and handles degenerate cases.

### 5.2.1 Types, macros and constants

`acb_poly_struct`

`acb_poly_t`

Contains a pointer to an array of coefficients (`coeffs`), the used length (`length`), and the allocated size of the array (`alloc`).

An `acb_poly_t` is defined as an array of length one of type `acb_poly_struct`, permitting an `acb_poly_t` to be passed by reference.

## 5.2.2 Memory management

void `acb_poly_init(acb_poly_t poly)`

Initializes the polynomial for use, setting it to the zero polynomial.

void `acb_poly_clear(acb_poly_t poly)`

Clears the polynomial, deallocating all coefficients and the coefficient array.

void `acb_poly_fit_length(acb_poly_t poly, slong len)`

Makes sure that the coefficient array of the polynomial contains at least `len` initialized coefficients.

void `_acb_poly_set_length(acb_poly_t poly, slong len)`

Directly changes the length of the polynomial, without allocating or deallocating coefficients. The value should not exceed the allocation length.

void `_acb_poly_normalise(acb_poly_t poly)`

Strips any trailing coefficients which are identical to zero.

void `acb_poly_swap(acb_poly_t poly1, acb_poly_t poly2)`

Swaps `poly1` and `poly2` efficiently.

slong `acb_poly_allocated_bytes(const acb_poly_t x)`

Returns the total number of bytes heap-allocated internally by this object. The count excludes the size of the structure itself. Add `sizeof(acb_poly_struct)` to get the size of the object as a whole.

## 5.2.3 Basic properties and manipulation

slong `acb_poly_length(const acb_poly_t poly)`

Returns the length of `poly`, i.e. zero if `poly` is identically zero, and otherwise one more than the index of the highest term that is not identically zero.

slong `acb_poly_degree(const acb_poly_t poly)`

Returns the degree of `poly`, defined as one less than its length. Note that if one or several leading coefficients are balls containing zero, this value can be larger than the true degree of the exact polynomial represented by `poly`, so the return value of this function is effectively an upper bound.

int `acb_poly_is_zero(const acb_poly_t poly)`

int `acb_poly_is_one(const acb_poly_t poly)`

int `acb_poly_is_x(const acb_poly_t poly)`

Returns 1 if `poly` is exactly the polynomial 0, 1 or  $x$  respectively. Returns 0 otherwise.

void `acb_poly_zero(acb_poly_t poly)`

Sets `poly` to the zero polynomial.

void `acb_poly_one(acb_poly_t poly)`

Sets `poly` to the constant polynomial 1.

void `acb_poly_set(acb_poly_t dest, const acb_poly_t src)`

Sets `dest` to a copy of `src`.

void `acb_poly_set_round(acb_poly_t dest, const acb_poly_t src, slong prec)`

Sets `dest` to a copy of `src`, rounded to `prec` bits.

void `acb_poly_set_trunc(acb_poly_t dest, const acb_poly_t src, slong n)`

void `acb_poly_set_trunc_round(acb_poly_t dest, const acb_poly_t src, slong n, slong prec)`

Sets `dest` to a copy of `src`, truncated to length `n` and rounded to `prec` bits.

void `acb_poly_set_coeff_si(acb_poly_t poly, slong n, slong c)`

void **acb\_poly\_set\_coeff\_acb**(*acb\_poly\_t poly*, *slong n*, const *acb\_t c*)  
Sets the coefficient with index  $n$  in *poly* to the value  $c$ . We require that  $n$  is nonnegative.

void **acb\_poly\_get\_coeff\_acb**(*acb\_t v*, const *acb\_poly\_t poly*, *slong n*)  
Sets  $v$  to the value of the coefficient with index  $n$  in *poly*. We require that  $n$  is nonnegative.

**acb\_poly\_get\_coeff\_ptr**(*poly*,  $n$ )  
Given  $n \geq 0$ , returns a pointer to coefficient  $n$  of *poly*, or *NULL* if  $n$  exceeds the length of *poly*.

void **\_acb\_poly\_shift\_right**(*acb\_ptr res*, *acb\_srcptr poly*, *slong len*, *slong n*)

void **acb\_poly\_shift\_right**(*acb\_poly\_t res*, const *acb\_poly\_t poly*, *slong n*)  
Sets *res* to *poly* divided by  $x^n$ , throwing away the lower coefficients. We require that  $n$  is nonnegative.

void **\_acb\_poly\_shift\_left**(*acb\_ptr res*, *acb\_srcptr poly*, *slong len*, *slong n*)

void **acb\_poly\_shift\_left**(*acb\_poly\_t res*, const *acb\_poly\_t poly*, *slong n*)  
Sets *res* to *poly* multiplied by  $x^n$ . We require that  $n$  is nonnegative.

void **acb\_poly\_truncate**(*acb\_poly\_t poly*, *slong n*)  
Truncates *poly* to have length at most  $n$ , i.e. degree strictly smaller than  $n$ . We require that  $n$  is nonnegative.

*slong* **acb\_poly\_valuation**(const *acb\_poly\_t poly*)  
Returns the degree of the lowest term that is not exactly zero in *poly*. Returns -1 if *poly* is the zero polynomial.

## 5.2.4 Input and output

void **acb\_poly\_printd**(const *acb\_poly\_t poly*, *slong digits*)  
Prints the polynomial as an array of coefficients, printing each coefficient using *acb\_printd*.

void **acb\_poly\_fprintd**(FILE \* *file*, const *acb\_poly\_t poly*, *slong digits*)  
Prints the polynomial as an array of coefficients to the stream *file*, printing each coefficient using *acb\_fprintd*.

## 5.2.5 Random generation

void **acb\_poly\_randtest**(*acb\_poly\_t poly*, *flint\_rand\_t state*, *slong len*, *slong prec*,  
*slong mag\_bits*)  
Creates a random polynomial with length at most *len*.

## 5.2.6 Comparisons

int **acb\_poly\_equal**(const *acb\_poly\_t A*, const *acb\_poly\_t B*)  
Returns nonzero iff  $A$  and  $B$  are identical as interval polynomials.

int **acb\_poly\_contains**(const *acb\_poly\_t poly1*, const *acb\_poly\_t poly2*)

int **acb\_poly\_contains\_fmpz\_poly**(const *acb\_poly\_t poly1*, const *fmpz\_poly\_t poly2*)

int **acb\_poly\_contains\_fmpq\_poly**(const *acb\_poly\_t poly1*, const *fmpq\_poly\_t poly2*)  
Returns nonzero iff *poly2* is contained in *poly1*.

int **\_acb\_poly\_overlaps**(*acb\_srcptr poly1*, *slong len1*, *acb\_srcptr poly2*, *slong len2*)

int **acb\_poly\_overlaps**(const *acb\_poly\_t poly1*, const *acb\_poly\_t poly2*)  
Returns nonzero iff *poly1* overlaps with *poly2*. The underscore function requires that *len1* is at least as large as *len2*.

`int acb_poly_get_unique_fmpz_poly(fmpz_poly_t z, const acb_poly_t x)`  
 If  $x$  contains a unique integer polynomial, sets  $z$  to that value and returns nonzero. Otherwise (if  $x$  represents no integers or more than one integer), returns zero, possibly partially modifying  $z$ .

`int acb_poly_is_real(const acb_poly_t poly)`  
 Returns nonzero iff all coefficients in  $poly$  have zero imaginary part.

### 5.2.7 Conversions

`void acb_poly_set_fmpz_poly(acb_poly_t poly, const fmpz_poly_t re, slong prec)`  
`void acb_poly_set2_fmpz_poly(acb_poly_t poly, const fmpz_poly_t re, const fmpz_poly_t im, slong prec)`  
`void acb_poly_set_arb_poly(acb_poly_t poly, const arb_poly_t re)`  
`void acb_poly_set2_arb_poly(acb_poly_t poly, const arb_poly_t re, const arb_poly_t im)`  
`void acb_poly_set_fmpq_poly(acb_poly_t poly, const fmpq_poly_t re, slong prec)`  
`void acb_poly_set2_fmpq_poly(acb_poly_t poly, const fmpq_poly_t re, const fmpq_poly_t im, slong prec)`  
 Sets  $poly$  to the given real part  $re$  plus the imaginary part  $im$ , both rounded to  $prec$  bits.  
`void acb_poly_set_acb(acb_poly_t poly, slong src)`  
`void acb_poly_set_si(acb_poly_t poly, slong src)`  
 Sets  $poly$  to  $src$ .

### 5.2.8 Bounds

`void _acb_poly_majorant(arb_ptr res, acb_srcptr poly, slong len, slong prec)`  
`void acb_poly_majorant(arb_poly_t res, const acb_poly_t poly, slong prec)`  
 Sets  $res$  to an exact real polynomial whose coefficients are upper bounds for the absolute values of the coefficients in  $poly$ , rounded to  $prec$  bits.

### 5.2.9 Arithmetic

`void _acb_poly_add(acb_ptr C, acb_srcptr A, slong lenA, acb_srcptr B, slong lenB, slong prec)`  
 Sets  $\{C, \max(lenA, lenB)\}$  to the sum of  $\{A, lenA\}$  and  $\{B, lenB\}$ . Allows aliasing of the input and output operands.  
`void acb_poly_add(acb_poly_t C, const acb_poly_t A, const acb_poly_t B, slong prec)`  
`void acb_poly_add_si(acb_poly_t C, const acb_poly_t A, slong B, slong prec)`  
 Sets  $C$  to the sum of  $A$  and  $B$ .  
`void _acb_poly_sub(acb_ptr C, acb_srcptr A, slong lenA, acb_srcptr B, slong lenB, slong prec)`  
 Sets  $\{C, \max(lenA, lenB)\}$  to the difference of  $\{A, lenA\}$  and  $\{B, lenB\}$ . Allows aliasing of the input and output operands.  
`void acb_poly_sub(acb_poly_t C, const acb_poly_t A, const acb_poly_t B, slong prec)`  
 Sets  $C$  to the difference of  $A$  and  $B$ .  
`void acb_poly_add_series(acb_poly_t C, const acb_poly_t A, const acb_poly_t B, slong len, slong prec)`  
 Sets  $C$  to the sum of  $A$  and  $B$ , truncated to length  $len$ .  
`void acb_poly_sub_series(acb_poly_t C, const acb_poly_t A, const acb_poly_t B, slong len, slong prec)`  
 Sets  $C$  to the difference of  $A$  and  $B$ , truncated to length  $len$ .

void **acb\_poly\_neg**(*acb\_poly\_t* C, const *acb\_poly\_t* A)  
Sets *C* to the negation of *A*.

void **acb\_poly\_scalar\_mul\_2exp\_si**(*acb\_poly\_t* C, const *acb\_poly\_t* A, *slong* c)  
Sets *C* to *A* multiplied by  $2^c$ .

void **acb\_poly\_scalar\_mul**(*acb\_poly\_t* C, const *acb\_poly\_t* A, const *acb\_t* c, *slong* prec)  
Sets *C* to *A* multiplied by *c*.

void **acb\_poly\_scalar\_div**(*acb\_poly\_t* C, const *acb\_poly\_t* A, const *acb\_t* c, *slong* prec)  
Sets *C* to *A* divided by *c*.

void **\_acb\_poly\_mulow\_classical**(*acb\_ptr* C, *acb\_srcptr* A, *slong* lenA, *acb\_srcptr* B, *slong* lenB, *slong* n, *slong* prec)

void **\_acb\_poly\_mulow\_transpose**(*acb\_ptr* C, *acb\_srcptr* A, *slong* lenA, *acb\_srcptr* B, *slong* lenB, *slong* n, *slong* prec)

void **\_acb\_poly\_mulow\_transpose\_gauss**(*acb\_ptr* C, *acb\_srcptr* A, *slong* lenA, *acb\_srcptr* B, *slong* lenB, *slong* n, *slong* prec)

void **\_acb\_poly\_mulow**(*acb\_ptr* C, *acb\_srcptr* A, *slong* lenA, *acb\_srcptr* B, *slong* lenB, *slong* n, *slong* prec)

Sets  $\{C, n\}$  to the product of  $\{A, lenA\}$  and  $\{B, lenB\}$ , truncated to length *n*. The output is not allowed to be aliased with either of the inputs. We require  $lenA \geq lenB > 0$ ,  $n > 0$ ,  $lenA + lenB - 1 \geq n$ .

The *classical* version uses a plain loop.

The *transpose* version evaluates the product using four real polynomial multiplications (via **\_arb\_poly\_mulow()**).

The *transpose\_gauss* version evaluates the product using three real polynomial multiplications. This is almost always faster than *transpose*, but has worse numerical stability when the coefficients vary in magnitude.

The default function **\_acb\_poly\_mulow()** automatically switches between *classical* and *transpose* multiplication.

If the input pointers are identical (and the lengths are the same), they are assumed to represent the same polynomial, and its square is computed.

void **acb\_poly\_mulow\_classical**(*acb\_poly\_t* C, const *acb\_poly\_t* A, const *acb\_poly\_t* B, *slong* n, *slong* prec)

void **acb\_poly\_mulow\_transpose**(*acb\_poly\_t* C, const *acb\_poly\_t* A, const *acb\_poly\_t* B, *slong* n, *slong* prec)

void **acb\_poly\_mulow\_transpose\_gauss**(*acb\_poly\_t* C, const *acb\_poly\_t* A, const *acb\_poly\_t* B, *slong* n, *slong* prec)

void **acb\_poly\_mulow**(*acb\_poly\_t* C, const *acb\_poly\_t* A, const *acb\_poly\_t* B, *slong* n, *slong* prec)

Sets *C* to the product of *A* and *B*, truncated to length *n*. If the same variable is passed for *A* and *B*, sets *C* to the square of *A* truncated to length *n*.

void **\_acb\_poly\_mul**(*acb\_ptr* C, *acb\_srcptr* A, *slong* lenA, *acb\_srcptr* B, *slong* lenB, *slong* prec)

Sets  $\{C, lenA + lenB - 1\}$  to the product of  $\{A, lenA\}$  and  $\{B, lenB\}$ . The output is not allowed to be aliased with either of the inputs. We require  $lenA \geq lenB > 0$ . This function is implemented as a simple wrapper for **\_acb\_poly\_mulow()**.

If the input pointers are identical (and the lengths are the same), they are assumed to represent the same polynomial, and its square is computed.

void **acb\_poly\_mul**(*acb\_poly\_t* C, const *acb\_poly\_t* A1, const *acb\_poly\_t* B2, *slong* prec)

Sets *C* to the product of *A* and *B*. If the same variable is passed for *A* and *B*, sets *C* to the square of *A*.

void `_acb_poly_inv_series`(*acb\_ptr* *Qinv*, *acb\_srcptr* *Q*, *slong* *Qlen*, *slong* *len*, *slong* *prec*)  
 Sets  $\{Qinv, len\}$  to the power series inverse of  $\{Q, Qlen\}$ . Uses Newton iteration.

void `acb_poly_inv_series`(*acb\_poly\_t* *Qinv*, const *acb\_poly\_t* *Q*, *slong* *n*, *slong* *prec*)  
 Sets *Qinv* to the power series inverse of *Q*.

void `_acb_poly_div_series`(*acb\_ptr* *Q*, *acb\_srcptr* *A*, *slong* *Alen*, *acb\_srcptr* *B*, *slong* *Blen*,  
*slong* *n*, *slong* *prec*)  
 Sets  $\{Q, n\}$  to the power series quotient of  $\{A, Alen\}$  by  $\{B, Blen\}$ . Uses Newton iteration followed by multiplication.

void `acb_poly_div_series`(*acb\_poly\_t* *Q*, const *acb\_poly\_t* *A*, const *acb\_poly\_t* *B*, *slong* *n*,  
*slong* *prec*)  
 Sets *Q* to the power series quotient *A* divided by *B*, truncated to length *n*.

void `_acb_poly_div`(*acb\_ptr* *Q*, *acb\_srcptr* *A*, *slong* *lenA*, *acb\_srcptr* *B*, *slong* *lenB*, *slong* *prec*)

void `_acb_poly_rem`(*acb\_ptr* *R*, *acb\_srcptr* *A*, *slong* *lenA*, *acb\_srcptr* *B*, *slong* *lenB*, *slong* *prec*)

void `_acb_poly_divrem`(*acb\_ptr* *Q*, *acb\_ptr* *R*, *acb\_srcptr* *A*, *slong* *lenA*, *acb\_srcptr* *B*,  
*slong* *lenB*, *slong* *prec*)

int `acb_poly_divrem`(*acb\_poly\_t* *Q*, *acb\_poly\_t* *R*, const *acb\_poly\_t* *A*, const *acb\_poly\_t* *B*,  
*slong* *prec*)  
 Performs polynomial division with remainder, computing a quotient *Q* and a remainder *R* such that  $A = BQ + R$ . The implementation reverses the inputs and performs power series division.

If the leading coefficient of *B* contains zero (or if *B* is identically zero), returns 0 indicating failure without modifying the outputs. Otherwise returns nonzero.

void `_acb_poly_div_root`(*acb\_ptr* *Q*, *acb\_t* *R*, *acb\_srcptr* *A*, *slong* *len*, const *acb\_t* *c*,  
*slong* *prec*)  
 Divides *A* by the polynomial  $x - c$ , computing the quotient *Q* as well as the remainder  $R = f(c)$ .

### 5.2.10 Composition

void `_acb_poly_taylor_shift_horner`(*acb\_ptr* *g*, const *acb\_t* *c*, *slong* *n*, *slong* *prec*)

void `acb_poly_taylor_shift_horner`(*acb\_poly\_t* *g*, const *acb\_poly\_t* *f*, const *acb\_t* *c*,  
*slong* *prec*)

void `_acb_poly_taylor_shift_divconquer`(*acb\_ptr* *g*, const *acb\_t* *c*, *slong* *n*, *slong* *prec*)

void `acb_poly_taylor_shift_divconquer`(*acb\_poly\_t* *g*, const *acb\_poly\_t* *f*, const *acb\_t* *c*,  
*slong* *prec*)

void `_acb_poly_taylor_shift_convolution`(*acb\_ptr* *g*, const *acb\_t* *c*, *slong* *n*, *slong* *prec*)

void `acb_poly_taylor_shift_convolution`(*acb\_poly\_t* *g*, const *acb\_poly\_t* *f*, const *acb\_t* *c*,  
*slong* *prec*)

void `_acb_poly_taylor_shift`(*acb\_ptr* *g*, const *acb\_t* *c*, *slong* *n*, *slong* *prec*)

void `acb_poly_taylor_shift`(*acb\_poly\_t* *g*, const *acb\_poly\_t* *f*, const *acb\_t* *c*, *slong* *prec*)  
 Sets *g* to the Taylor shift  $f(x + c)$ , computed respectively using an optimized form of Horner's rule, divide-and-conquer, a single convolution, and an automatic choice between the three algorithms.

The underscore methods act in-place on  $g = f$  which has length *n*.

void `_acb_poly_compose_horner`(*acb\_ptr* *res*, *acb\_srcptr* *poly1*, *slong* *len1*, *acb\_srcptr* *poly2*,  
*slong* *len2*, *slong* *prec*)

void `acb_poly_compose_horner`(*acb\_poly\_t* *res*, const *acb\_poly\_t* *poly1*, const *acb\_poly\_t* *poly2*,  
*slong* *prec*)

void `_acb_poly_compose_divconquer`(*acb\_ptr* *res*, *acb\_srcptr* *poly1*, *slong* *len1*,  
*acb\_srcptr* *poly2*, *slong* *len2*, *slong* *prec*)

void `acb_poly_compose_divconquer`(*acb\_poly\_t* *res*, const *acb\_poly\_t* *poly1*, const  
*acb\_poly\_t* *poly2*, *slong* *prec*)

```
void _acb_poly_compose(acb_ptr res, acb_srcptr poly1, slong len1, acb_srcptr poly2, slong len2,
                      slong prec)
```

```
void acb_poly_compose(acb_poly_t res, const acb_poly_t poly1, const acb_poly_t poly2,
                      slong prec)
```

Sets *res* to the composition  $h(x) = f(g(x))$  where  $f$  is given by *poly1* and  $g$  is given by *poly2*, respectively using Horner's rule, divide-and-conquer, and an automatic choice between the two algorithms.

The default algorithm also handles special-form input  $g = ax^n + c$  efficiently by performing a Taylor shift followed by a rescaling.

The underscore methods do not support aliasing of the output with either input polynomial.

```
void _acb_poly_compose_series_horner(acb_ptr res, acb_srcptr poly1, slong len1,
                                     acb_srcptr poly2, slong len2, slong n, slong prec)
```

```
void acb_poly_compose_series_horner(acb_poly_t res, const acb_poly_t poly1, const
                                     acb_poly_t poly2, slong n, slong prec)
```

```
void _acb_poly_compose_series_brent_kung(acb_ptr res, acb_srcptr poly1, slong len1,
                                          acb_srcptr poly2, slong len2, slong n, slong prec)
```

```
void acb_poly_compose_series_brent_kung(acb_poly_t res, const acb_poly_t poly1, const
                                          acb_poly_t poly2, slong n, slong prec)
```

```
void _acb_poly_compose_series(acb_ptr res, acb_srcptr poly1, slong len1, acb_srcptr poly2,
                              slong len2, slong n, slong prec)
```

```
void acb_poly_compose_series(acb_poly_t res, const acb_poly_t poly1, const acb_poly_t poly2,
                              slong n, slong prec)
```

Sets *res* to the power series composition  $h(x) = f(g(x))$  truncated to order  $O(x^n)$  where  $f$  is given by *poly1* and  $g$  is given by *poly2*, respectively using Horner's rule, the Brent-Kung baby step-giant step algorithm, and an automatic choice between the two algorithms.

The default algorithm also handles special-form input  $g = ax^n$  efficiently.

We require that the constant term in  $g(x)$  is exactly zero. The underscore methods do not support aliasing of the output with either input polynomial.

```
void _acb_poly_revert_series_lagrange(acb_ptr h, acb_srcptr f, slong flen, slong n,
                                     slong prec)
```

```
void acb_poly_revert_series_lagrange(acb_poly_t h, const acb_poly_t f, slong n, slong prec)
```

```
void _acb_poly_revert_series_newton(acb_ptr h, acb_srcptr f, slong flen, slong n, slong prec)
```

```
void acb_poly_revert_series_newton(acb_poly_t h, const acb_poly_t f, slong n, slong prec)
```

```
void _acb_poly_revert_series_lagrange_fast(acb_ptr h, acb_srcptr f, slong flen, slong n,
                                           slong prec)
```

```
void acb_poly_revert_series_lagrange_fast(acb_poly_t h, const acb_poly_t f, slong n,
                                           slong prec)
```

```
void _acb_poly_revert_series(acb_ptr h, acb_srcptr f, slong flen, slong n, slong prec)
```

```
void acb_poly_revert_series(acb_poly_t h, const acb_poly_t f, slong n, slong prec)
```

Sets *h* to the power series reversion of *f*, i.e. the expansion of the compositional inverse function  $f^{-1}(x)$ , truncated to order  $O(x^n)$ , using respectively Lagrange inversion, Newton iteration, fast Lagrange inversion, and a default algorithm choice.

We require that the constant term in *f* is exactly zero and that the linear term is nonzero. The underscore methods assume that *flen* is at least 2, and do not support aliasing.

### 5.2.11 Evaluation

```
void _acb_poly_evaluate_horner(acb_t y, acb_srcptr f, slong len, const acb_t x, slong prec)
```

```
void acb_poly_evaluate_horner(acb_t y, const acb_poly_t f, const acb_t x, slong prec)
```

```
void _acb_poly_evaluate_rectangular(acb_t y, acb_srcptr f, slong len, const acb_t x,
                                   slong prec)
void acb_poly_evaluate_rectangular(acb_t y, const acb_poly_t f, const acb_t x, slong prec)
void _acb_poly_evaluate(acb_t y, acb_srcptr f, slong len, const acb_t x, slong prec)
void acb_poly_evaluate(acb_t y, const acb_poly_t f, const acb_t x, slong prec)
    Sets  $y = f(x)$ , evaluated respectively using Horner's rule, rectangular splitting, and an automatic
    algorithm choice.
void _acb_poly_evaluate2_horner(acb_t y, acb_t z, acb_srcptr f, slong len, const acb_t x,
                               slong prec)
void acb_poly_evaluate2_horner(acb_t y, acb_t z, const acb_poly_t f, const acb_t x,
                              slong prec)
void _acb_poly_evaluate2_rectangular(acb_t y, acb_t z, acb_srcptr f, slong len, const
                                    acb_t x, slong prec)
void acb_poly_evaluate2_rectangular(acb_t y, acb_t z, const acb_poly_t f, const acb_t x,
                                   slong prec)
void _acb_poly_evaluate2(acb_t y, acb_t z, acb_srcptr f, slong len, const acb_t x, slong prec)
void acb_poly_evaluate2(acb_t y, acb_t z, const acb_poly_t f, const acb_t x, slong prec)
    Sets  $y = f(x)$ ,  $z = f'(x)$ , evaluated respectively using Horner's rule, rectangular splitting, and an
    automatic algorithm choice.
```

When Horner's rule is used, the only advantage of evaluating the function and its derivative simultaneously is that one does not have to generate the derivative polynomial explicitly. With the rectangular splitting algorithm, the powers can be reused, making simultaneous evaluation slightly faster.

### 5.2.12 Product trees

```
void _acb_poly_product_roots(acb_ptr poly, acb_srcptr xs, slong n, slong prec)
void acb_poly_product_roots(acb_poly_t poly, acb_srcptr xs, slong n, slong prec)
    Generates the polynomial  $(x - x_0)(x - x_1) \cdots (x - x_{n-1})$ .
acb_ptr * _acb_poly_tree_alloc(slong len)
    Returns an initialized data structured capable of representing a remainder tree (product tree) of
    len roots.
void _acb_poly_tree_free(acb_ptr * tree, slong len)
    Deallocates a tree structure as allocated using _acb_poly_tree_alloc.
void _acb_poly_tree_build(acb_ptr * tree, acb_srcptr roots, slong len, slong prec)
    Constructs a product tree from a given array of len roots. The tree structure must be pre-allocated
    to the specified length using _acb_poly_tree_alloc().
```

### 5.2.13 Multipoint evaluation

```
void _acb_poly_evaluate_vec_iter(acb_ptr ys, acb_srcptr poly, slong plen, acb_srcptr xs,
                                slong n, slong prec)
void acb_poly_evaluate_vec_iter(acb_ptr ys, const acb_poly_t poly, acb_srcptr xs, slong n,
                                slong prec)
    Evaluates the polynomial simultaneously at  $n$  given points, calling _acb_poly_evaluate() re-
    peatedly.
void _acb_poly_evaluate_vec_fast_precomp(acb_ptr vs, acb_srcptr poly, slong plen, acb_ptr
                                         * tree, slong len, slong prec)
void _acb_poly_evaluate_vec_fast(acb_ptr ys, acb_srcptr poly, slong plen, acb_srcptr xs,
                                slong n, slong prec)
```

void **acb\_poly\_evaluate\_vec\_fast**(*acb\_ptr* *ys*, const *acb\_poly\_t* *poly*, *acb\_srcptr* *xs*, *slong* *n*,  
*slong* *prec*)

Evaluates the polynomial simultaneously at  $n$  given points, using fast multipoint evaluation.

### 5.2.14 Interpolation

void **\_acb\_poly\_interpolate\_newton**(*acb\_ptr* *poly*, *acb\_srcptr* *xs*, *acb\_srcptr* *ys*, *slong* *n*,  
*slong* *prec*)

void **acb\_poly\_interpolate\_newton**(*acb\_poly\_t* *poly*, *acb\_srcptr* *xs*, *acb\_srcptr* *ys*, *slong* *n*,  
*slong* *prec*)

Recovers the unique polynomial of length at most  $n$  that interpolates the given  $x$  and  $y$  values. This implementation first interpolates in the Newton basis and then converts back to the monomial basis.

void **\_acb\_poly\_interpolate\_barycentric**(*acb\_ptr* *poly*, *acb\_srcptr* *xs*, *acb\_srcptr* *ys*, *slong* *n*,  
*slong* *prec*)

void **acb\_poly\_interpolate\_barycentric**(*acb\_poly\_t* *poly*, *acb\_srcptr* *xs*, *acb\_srcptr* *ys*,  
*slong* *n*, *slong* *prec*)

Recovers the unique polynomial of length at most  $n$  that interpolates the given  $x$  and  $y$  values. This implementation uses the barycentric form of Lagrange interpolation.

void **\_acb\_poly\_interpolation\_weights**(*acb\_ptr* *w*, *acb\_ptr* \* *tree*, *slong* *len*, *slong* *prec*)

void **\_acb\_poly\_interpolate\_fast\_precomp**(*acb\_ptr* *poly*, *acb\_srcptr* *ys*, *acb\_ptr* \* *tree*,  
*acb\_srcptr* *weights*, *slong* *len*, *slong* *prec*)

void **\_acb\_poly\_interpolate\_fast**(*acb\_ptr* *poly*, *acb\_srcptr* *xs*, *acb\_srcptr* *ys*, *slong* *len*,  
*slong* *prec*)

void **acb\_poly\_interpolate\_fast**(*acb\_poly\_t* *poly*, *acb\_srcptr* *xs*, *acb\_srcptr* *ys*, *slong* *n*,  
*slong* *prec*)

Recovers the unique polynomial of length at most  $n$  that interpolates the given  $x$  and  $y$  values, using fast Lagrange interpolation. The precomp function takes a precomputed product tree over the  $x$  values and a vector of interpolation weights as additional inputs.

### 5.2.15 Differentiation

void **\_acb\_poly\_derivative**(*acb\_ptr* *res*, *acb\_srcptr* *poly*, *slong* *len*, *slong* *prec*)

Sets  $\{res, len - 1\}$  to the derivative of  $\{poly, len\}$ . Allows aliasing of the input and output.

void **acb\_poly\_derivative**(*acb\_poly\_t* *res*, const *acb\_poly\_t* *poly*, *slong* *prec*)

Sets *res* to the derivative of *poly*.

void **\_acb\_poly\_integral**(*acb\_ptr* *res*, *acb\_srcptr* *poly*, *slong* *len*, *slong* *prec*)

Sets  $\{res, len\}$  to the integral of  $\{poly, len - 1\}$ . Allows aliasing of the input and output.

void **acb\_poly\_integral**(*acb\_poly\_t* *res*, const *acb\_poly\_t* *poly*, *slong* *prec*)

Sets *res* to the integral of *poly*.

### 5.2.16 Transforms

void **\_acb\_poly\_borel\_transform**(*acb\_ptr* *res*, *acb\_srcptr* *poly*, *slong* *len*, *slong* *prec*)

void **acb\_poly\_borel\_transform**(*acb\_poly\_t* *res*, const *acb\_poly\_t* *poly*, *slong* *prec*)

Computes the Borel transform of the input polynomial, mapping  $\sum_k a_k x^k$  to  $\sum_k (a_k/k!) x^k$ . The underscore method allows aliasing.

void **\_acb\_poly\_inv\_borel\_transform**(*acb\_ptr* *res*, *acb\_srcptr* *poly*, *slong* *len*, *slong* *prec*)

void **acb\_poly\_inv\_borel\_transform**(*acb\_poly\_t* *res*, const *acb\_poly\_t* *poly*, *slong* *prec*)

Computes the inverse Borel transform of the input polynomial, mapping  $\sum_k a_k x^k$  to  $\sum_k a_k k! x^k$ . The underscore method allows aliasing.

```
void _acb_poly_binomial_transform_basecase(acb_ptr b, acb_srcptr a, slong alen, slong len,
                                           slong prec)
void acb_poly_binomial_transform_basecase(acb_poly_t b, const acb_poly_t a, slong len,
                                           slong prec)
void _acb_poly_binomial_transform_convolution(acb_ptr b, acb_srcptr a, slong alen,
                                              slong len, slong prec)
void acb_poly_binomial_transform_convolution(acb_poly_t b, const acb_poly_t a, slong len,
                                              slong prec)
void _acb_poly_binomial_transform(acb_ptr b, acb_srcptr a, slong alen, slong len, slong prec)
void acb_poly_binomial_transform(acb_poly_t b, const acb_poly_t a, slong len, slong prec)
    Computes the binomial transform of the input polynomial, truncating the output to length len.
    See arb\_poly\_binomial\_transform\(\) for details.
```

The underscore methods do not support aliasing, and assume that the lengths are nonzero.

## 5.2.17 Elementary functions

```
void _acb_poly_pow_ui_trunc_binexp(acb_ptr res, acb_srcptr f, slong flen, ulong exp, slong len,
                                   slong prec)
    Sets  $\{res, len\}$  to  $\{f, flen\}$  raised to the power exp, truncated to length len. Requires that len is
    no longer than the length of the power as computed without truncation (i.e. no zero-padding is
    performed). Does not support aliasing of the input and output, and requires that flen and len are
    positive. Uses binary exponentiation.
void acb_poly_pow_ui_trunc_binexp(acb_poly_t res, const acb_poly_t poly, ulong exp,
                                   slong len, slong prec)
    Sets res to poly raised to the power exp, truncated to length len. Uses binary exponentiation.
void _acb_poly_pow_ui(acb_ptr res, acb_srcptr f, slong flen, ulong exp, slong prec)
    Sets res to  $\{f, flen\}$  raised to the power exp. Does not support aliasing of the input and output,
    and requires that flen is positive.
void acb_poly_pow_ui(acb_poly_t res, const acb_poly_t poly, ulong exp, slong prec)
    Sets res to poly raised to the power exp.
void _acb_poly_pow_series(acb_ptr h, acb_srcptr f, slong flen, acb_srcptr g, slong glen,
                          slong len, slong prec)
    Sets  $\{h, len\}$  to the power series  $f(x)^{g(x)} = \exp(g(x) \log f(x))$  truncated to length len. This
    function detects special cases such as g being an exact small integer or  $\pm 1/2$ , and computes such
    powers more efficiently. This function does not support aliasing of the output with either of the
    input operands. It requires that all lengths are positive, and assumes that flen and glen do not
    exceed len.
void acb_poly_pow_series(acb_poly_t h, const acb_poly_t f, const acb_poly_t g, slong len,
                          slong prec)
    Sets h to the power series  $f(x)^{g(x)} = \exp(g(x) \log f(x))$  truncated to length len. This function
    detects special cases such as g being an exact small integer or  $\pm 1/2$ , and computes such powers
    more efficiently.
void _acb_poly_pow_acb_series(acb_ptr h, acb_srcptr f, slong flen, const acb_t g, slong len,
                              slong prec)
    Sets  $\{h, len\}$  to the power series  $f(x)^g = \exp(g \log f(x))$  truncated to length len. This function
    detects special cases such as g being an exact small integer or  $\pm 1/2$ , and computes such powers
    more efficiently. This function does not support aliasing of the output with either of the input
    operands. It requires that all lengths are positive, and assumes that flen does not exceed len.
void acb_poly_pow_acb_series(acb_poly_t h, const acb_poly_t f, const acb_t g, slong len,
                              slong prec)
    Sets h to the power series  $f(x)^g = \exp(g \log f(x))$  truncated to length len.
void _acb_poly_sqrt_series(acb_ptr g, acb_srcptr h, slong hlen, slong n, slong prec)
```

void **acb\_poly\_sqrt\_series**(*acb\_poly\_t* g, const *acb\_poly\_t* h, *slong* n, *slong* prec)

Sets *g* to the power series square root of *h*, truncated to length *n*. Uses division-free Newton iteration for the reciprocal square root, followed by a multiplication.

The underscore method does not support aliasing of the input and output arrays. It requires that *hlen* and *n* are greater than zero.

void **\_acb\_poly\_rsqrt\_series**(*acb\_ptr* g, *acb\_srcptr* h, *slong* hlen, *slong* n, *slong* prec)

void **acb\_poly\_rsqrt\_series**(*acb\_poly\_t* g, const *acb\_poly\_t* h, *slong* n, *slong* prec)

Sets *g* to the reciprocal power series square root of *h*, truncated to length *n*. Uses division-free Newton iteration.

The underscore method does not support aliasing of the input and output arrays. It requires that *hlen* and *n* are greater than zero.

void **\_acb\_poly\_log\_series**(*acb\_ptr* res, *acb\_srcptr* f, *slong* flen, *slong* n, *slong* prec)

void **acb\_poly\_log\_series**(*acb\_poly\_t* res, const *acb\_poly\_t* f, *slong* n, *slong* prec)

Sets *res* to the power series logarithm of *f*, truncated to length *n*. Uses the formula  $\log(f(x)) = \int f'(x)/f(x)dx$ , adding the logarithm of the constant term in *f* as the constant of integration.

The underscore method supports aliasing of the input and output arrays. It requires that *flen* and *n* are greater than zero.

void **\_acb\_poly\_log1p\_series**(*acb\_ptr* res, *acb\_srcptr* f, *slong* flen, *slong* n, *slong* prec)

void **acb\_poly\_log1p\_series**(*acb\_poly\_t* res, const *acb\_poly\_t* f, *slong* n, *slong* prec)

Computes the power series  $\log(1 + f)$ , with better accuracy when the constant term of *f* is small.

void **\_acb\_poly\_atan\_series**(*acb\_ptr* res, *acb\_srcptr* f, *slong* flen, *slong* n, *slong* prec)

void **acb\_poly\_atan\_series**(*acb\_poly\_t* res, const *acb\_poly\_t* f, *slong* n, *slong* prec)

Sets *res* the power series inverse tangent of *f*, truncated to length *n*.

Uses the formula

$$\tan^{-1}(f(x)) = \int f'(x)/(1 + f(x)^2)dx,$$

adding the function of the constant term in *f* as the constant of integration.

The underscore method supports aliasing of the input and output arrays. It requires that *flen* and *n* are greater than zero.

void **\_acb\_poly\_exp\_series\_basecase**(*acb\_ptr* f, *acb\_srcptr* h, *slong* hlen, *slong* n, *slong* prec)

void **acb\_poly\_exp\_series\_basecase**(*acb\_poly\_t* f, const *acb\_poly\_t* h, *slong* n, *slong* prec)

void **\_acb\_poly\_exp\_series**(*acb\_ptr* f, *acb\_srcptr* h, *slong* hlen, *slong* n, *slong* prec)

void **acb\_poly\_exp\_series**(*acb\_poly\_t* f, const *acb\_poly\_t* h, *slong* n, *slong* prec)

Sets *f* to the power series exponential of *h*, truncated to length *n*.

The basecase version uses a simple recurrence for the coefficients, requiring  $O(nm)$  operations where *m* is the length of *h*.

The main implementation uses Newton iteration, starting from a small number of terms given by the basecase algorithm. The complexity is  $O(M(n))$ . Redundant operations in the Newton iteration are avoided by using the scheme described in [HZ2004].

The underscore methods support aliasing and allow the input to be shorter than the output, but require the lengths to be nonzero.

void **\_acb\_poly\_exp\_pi\_i\_series**(*acb\_ptr* f, *acb\_srcptr* h, *slong* hlen, *slong* n, *slong* prec)

void **acb\_poly\_exp\_pi\_i\_series**(*acb\_poly\_t* f, const *acb\_poly\_t* h, *slong* n, *slong* prec)

Sets *f* to the power series  $\exp(\pi i h)$  truncated to length *n*. The underscore method supports aliasing and allows the input to be shorter than the output, but requires the lengths to be nonzero.

```

void _acb_poly_sin_cos_series_basecase(acb_ptr s, acb_ptr c, acb_srcptr h, slong hlen,
                                       slong n, slong prec, int times_pi)
void acb_poly_sin_cos_series_basecase(acb_poly_t s, acb_poly_t c, const acb_poly_t h,
                                       slong n, slong prec, int times_pi)
void _acb_poly_sin_cos_series_tangent(acb_ptr s, acb_ptr c, acb_srcptr h, slong hlen,
                                       slong n, slong prec, int times_pi)
void acb_poly_sin_cos_series_tangent(acb_poly_t s, acb_poly_t c, const acb_poly_t h,
                                       slong n, slong prec, int times_pi)
void _acb_poly_sin_cos_series(acb_ptr s, acb_ptr c, acb_srcptr h, slong hlen, slong n,
                              slong prec)
void acb_poly_sin_cos_series(acb_poly_t s, acb_poly_t c, const acb_poly_t h, slong n,
                              slong prec)

```

Sets  $s$  and  $c$  to the power series sine and cosine of  $h$ , computed simultaneously.

The *basecase* version uses a simple recurrence for the coefficients, requiring  $O(nm)$  operations where  $m$  is the length of  $h$ .

The *tangent* version uses the tangent half-angle formulas to compute the sine and cosine via `_acb_poly_tan_series()`. This requires  $O(M(n))$  operations. When  $h = h_0 + h_1$  where the constant term  $h_0$  is nonzero, the evaluation is done as  $\sin(h_0 + h_1) = \cos(h_0)\sin(h_1) + \sin(h_0)\cos(h_1)$ ,  $\cos(h_0 + h_1) = \cos(h_0)\cos(h_1) - \sin(h_0)\sin(h_1)$ , to improve accuracy and avoid dividing by zero at the poles of the tangent function.

The default version automatically selects between the *basecase* and *tangent* algorithms depending on the input.

The *basecase* and *tangent* versions take a flag *times\_pi* specifying that the input is to be multiplied by  $\pi$ .

The underscore methods support aliasing and require the lengths to be nonzero.

```

void _acb_poly_sin_series(acb_ptr s, acb_srcptr h, slong hlen, slong n, slong prec)
void acb_poly_sin_series(acb_poly_t s, const acb_poly_t h, slong n, slong prec)
void _acb_poly_cos_series(acb_ptr c, acb_srcptr h, slong hlen, slong n, slong prec)
void acb_poly_cos_series(acb_poly_t c, const acb_poly_t h, slong n, slong prec)

```

Respectively evaluates the power series sine or cosine. These functions simply wrap `_acb_poly_sin_cos_series()`. The underscore methods support aliasing and require the lengths to be nonzero.

```

void _acb_poly_tan_series(acb_ptr g, acb_srcptr h, slong hlen, slong len, slong prec)
void acb_poly_tan_series(acb_poly_t g, const acb_poly_t h, slong n, slong prec)

```

Sets  $g$  to the power series tangent of  $h$ .

For small  $n$  takes the quotient of the sine and cosine as computed using the basecase algorithm. For large  $n$ , uses Newton iteration to invert the inverse tangent series. The complexity is  $O(M(n))$ .

The underscore version does not support aliasing, and requires the lengths to be nonzero.

```

void _acb_poly_sin_cos_pi_series(acb_ptr s, acb_ptr c, acb_srcptr h, slong hlen, slong n,
                                slong prec)
void acb_poly_sin_cos_pi_series(acb_poly_t s, acb_poly_t c, const acb_poly_t h, slong n,
                                slong prec)
void _acb_poly_sin_pi_series(acb_ptr s, acb_srcptr h, slong hlen, slong n, slong prec)
void acb_poly_sin_pi_series(acb_poly_t s, const acb_poly_t h, slong n, slong prec)
void _acb_poly_cos_pi_series(acb_ptr c, acb_srcptr h, slong hlen, slong n, slong prec)
void acb_poly_cos_pi_series(acb_poly_t c, const acb_poly_t h, slong n, slong prec)
void _acb_poly_cot_pi_series(acb_ptr c, acb_srcptr h, slong hlen, slong n, slong prec)

```

```
void acb_poly_cot_pi_series(acb_poly_t c, const acb_poly_t h, slong n, slong prec)
    Compute the respective trigonometric functions of the input multiplied by  $\pi$ .

void _acb_poly_sinh_cosh_series_basecase(acb_ptr s, acb_ptr c, acb_srcptr h, slong hlen,
                                         slong n, slong prec)

void acb_poly_sinh_cosh_series_basecase(acb_poly_t s, acb_poly_t c, const acb_poly_t h,
                                         slong n, slong prec)

void _acb_poly_sinh_cosh_series_exponential(acb_ptr s, acb_ptr c, acb_srcptr h, slong hlen,
                                             slong n, slong prec)

void acb_poly_sinh_cosh_series_exponential(acb_poly_t s, acb_poly_t c, const
                                           acb_poly_t h, slong n, slong prec)

void _acb_poly_sinh_cosh_series(acb_ptr s, acb_ptr c, acb_srcptr h, slong hlen, slong n,
                                slong prec)

void acb_poly_sinh_cosh_series(acb_poly_t s, acb_poly_t c, const acb_poly_t h, slong n,
                                slong prec)

void _acb_poly_sinh_series(acb_ptr s, acb_srcptr h, slong hlen, slong n, slong prec)

void acb_poly_sinh_series(acb_poly_t s, const acb_poly_t h, slong n, slong prec)

void _acb_poly_cosh_series(acb_ptr c, acb_srcptr h, slong hlen, slong n, slong prec)

void acb_poly_cosh_series(acb_poly_t c, const acb_poly_t h, slong n, slong prec)
    Sets s and c respectively to the hyperbolic sine and cosine of the power series h, truncated to length
    n.

    The implementations mirror those for sine and cosine, except that the exponential version computes
    both functions using the exponential function instead of the hyperbolic tangent.

void _acb_poly_sinc_series(acb_ptr s, acb_srcptr h, slong hlen, slong n, slong prec)

void acb_poly_sinc_series(acb_poly_t s, const acb_poly_t h, slong n, slong prec)
    Sets s to the sinc function of the power series h, truncated to length n.
```

### 5.2.18 Lambert W function

```
void _acb_poly_lambertw_series(acb_ptr res, acb_srcptr z, slong zlen, const fmpz_t k, int flags,
                              slong len, slong prec)

void acb_poly_lambertw_series(acb_poly_t res, const acb_poly_t z, const fmpz_t k, int flags,
                              slong len, slong prec)
    Sets res to branch k of the Lambert W function of the power series z. The argument flags is
    reserved for future use. The underscore method allows aliasing, but assumes that the lengths are
    nonzero.
```

### 5.2.19 Gamma function

```
void _acb_poly_gamma_series(acb_ptr res, acb_srcptr h, slong hlen, slong n, slong prec)

void acb_poly_gamma_series(acb_poly_t res, const acb_poly_t h, slong n, slong prec)

void _acb_poly_rgamma_series(acb_ptr res, acb_srcptr h, slong hlen, slong n, slong prec)

void acb_poly_rgamma_series(acb_poly_t res, const acb_poly_t h, slong n, slong prec)

void _acb_poly_lgamma_series(acb_ptr res, acb_srcptr h, slong hlen, slong n, slong prec)

void acb_poly_lgamma_series(acb_poly_t res, const acb_poly_t h, slong n, slong prec)

void _acb_poly_digamma_series(acb_ptr res, acb_srcptr h, slong hlen, slong n, slong prec)
```

void **acb\_poly\_digamma\_series**(*acb\_poly\_t* res, const *acb\_poly\_t* h, *slong* n, *slong* prec)  
 Sets *res* to the series expansion of  $\Gamma(h(x))$ ,  $1/\Gamma(h(x))$ , or  $\log \Gamma(h(x))$ ,  $\psi(h(x))$ , truncated to length *n*.

These functions first generate the Taylor series at the constant term of *h*, and then call **\_acb\_poly\_compose\_series()**. The Taylor coefficients are generated using Stirling's series.

The underscore methods support aliasing of the input and output arrays, and require that *hlen* and *n* are greater than zero.

void **\_acb\_poly\_rising\_ui\_series**(*acb\_ptr* res, *acb\_srcptr* f, *slong* flen, *ulong* r, *slong* trunc, *slong* prec)

void **acb\_poly\_rising\_ui\_series**(*acb\_poly\_t* res, const *acb\_poly\_t* f, *ulong* r, *slong* trunc, *slong* prec)

Sets *res* to the rising factorial  $(f)(f+1)(f+2)\cdots(f+r-1)$ , truncated to length *trunc*. The underscore method assumes that *flen*, *r* and *trunc* are at least 1, and does not support aliasing. Uses binary splitting.

## 5.2.20 Power sums

void **\_acb\_poly\_powsum\_series\_naive**(*acb\_ptr* z, const *acb\_t* s, const *acb\_t* a, const *acb\_t* q, *slong* n, *slong* len, *slong* prec)

void **\_acb\_poly\_powsum\_series\_naive\_threaded**(*acb\_ptr* z, const *acb\_t* s, const *acb\_t* a, const *acb\_t* q, *slong* n, *slong* len, *slong* prec)

Computes

$$z = S(s, a, n) = \sum_{k=0}^{n-1} \frac{q^k}{(k+a)^{s+t}}$$

as a power series in *t* truncated to length *len*. This function evaluates the sum naively term by term. The *threaded* version splits the computation over the number of threads returned by **flint\_get\_num\_threads()**.

void **\_acb\_poly\_powsum\_one\_series\_sieved**(*acb\_ptr* z, const *acb\_t* s, *slong* n, *slong* len, *slong* prec)

Computes

$$z = S(s, 1, n) \sum_{k=1}^n \frac{1}{k^{s+t}}$$

as a power series in *t* truncated to length *len*. This function stores a table of powers that have already been calculated, computing  $(ij)^r$  as  $i^r j^r$  whenever  $k = ij$  is composite. As a further optimization, it groups all even *k* and evaluates the sum as a polynomial in  $2^{-(s+t)}$ . This scheme requires about  $n/\log n$  powers,  $n/2$  multiplications, and temporary storage of  $n/6$  power series. Due to the extra power series multiplications, it is only faster than the naive algorithm when *len* is small.

## 5.2.21 Zeta function

void **\_acb\_poly\_zeta\_em\_choose\_param**(*mag\_t* bound, *ulong* \* N, *ulong* \* M, const *acb\_t* s, const *acb\_t* a, *slong* d, *slong* target, *slong* prec)

Chooses *N* and *M* for Euler-Maclaurin summation of the Hurwitz zeta function, using a default algorithm.

void **\_acb\_poly\_zeta\_em\_bound1**(*mag\_t* bound, const *acb\_t* s, const *acb\_t* a, *slong* N, *slong* M, *slong* d, *slong* wp)

void **\_acb\_poly\_zeta\_em\_bound**(*arb\_ptr* vec, const *acb\_t* s, const *acb\_t* a, *ulong* N, *ulong* M, *slong* d, *slong* wp)

Compute bounds for Euler-Maclaurin evaluation of the Hurwitz zeta function or its power series, using the formulas in [Joh2013].

void `_acb_poly_zeta_em_tail_naive`(*acb\_ptr* *z*, const *acb\_t* *s*, const *acb\_t* *Na*,  
*acb\_srcptr* *Nasx*, *slong* *M*, *slong* *len*, *slong* *prec*)

void `_acb_poly_zeta_em_tail_bsplt`(*acb\_ptr* *z*, const *acb\_t* *s*, const *acb\_t* *Na*,  
*acb\_srcptr* *Nasx*, *slong* *M*, *slong* *len*, *slong* *prec*)

Evaluates the tail in the Euler-Maclaurin sum for the Hurwitz zeta function, respectively using the naive recurrence and binary splitting.

void `_acb_poly_zeta_em_sum`(*acb\_ptr* *z*, const *acb\_t* *s*, const *acb\_t* *a*, int *deflate*, *ulong* *N*,  
*ulong* *M*, *slong* *d*, *slong* *prec*)

Evaluates the truncated Euler-Maclaurin sum of order  $N, M$  for the length- $d$  truncated Taylor series of the Hurwitz zeta function  $\zeta(s, a)$  at  $s$ , using a working precision of  $prec$  bits. With  $a = 1$ , this gives the usual Riemann zeta function.

If *deflate* is nonzero,  $\zeta(s, a) - 1/(s - 1)$  is evaluated (which permits series expansion at  $s = 1$ ).

void `_acb_poly_zeta_cpx_series`(*acb\_ptr* *z*, const *acb\_t* *s*, const *acb\_t* *a*, int *deflate*, *slong* *d*,  
*slong* *prec*)

Computes the series expansion of  $\zeta(s + x, a)$  (or  $\zeta(s + x, a) - 1/(s + x - 1)$  if *deflate* is nonzero) to order  $d$ .

This function wraps `_acb_poly_zeta_em_sum()`, automatically choosing default values for  $N, M$  using `_acb_poly_zeta_em_choose_param()` to target an absolute truncation error of  $2^{-prec}$ .

void `_acb_poly_zeta_series`(*acb\_ptr* *res*, *acb\_srcptr* *h*, *slong* *hlen*, const *acb\_t* *a*, int *deflate*,  
*slong* *len*, *slong* *prec*)

void `acb_poly_zeta_series`(*acb\_poly\_t* *res*, const *acb\_poly\_t* *f*, const *acb\_t* *a*, int *deflate*,  
*slong* *n*, *slong* *prec*)

Sets *res* to the Hurwitz zeta function  $\zeta(s, a)$  where  $s$  a power series and  $a$  is a constant, truncated to length  $n$ . To evaluate the usual Riemann zeta function, set  $a = 1$ .

If *deflate* is nonzero, evaluates  $\zeta(s, a) + 1/(1 - s)$ , which is well-defined as a limit when the constant term of  $s$  is 1. In particular, expanding  $\zeta(s, a) + 1/(1 - s)$  with  $s = 1 + x$  gives the Stieltjes constants

$$\sum_{k=0}^{n-1} \frac{(-1)^k}{k!} \gamma_k(a) x^k.$$

If  $a = 1$ , this implementation uses the reflection formula if the midpoint of the constant term of  $s$  is negative.

## 5.2.22 Other special functions

void `_acb_poly_polylog_cpx_small`(*acb\_ptr* *w*, const *acb\_t* *s*, const *acb\_t* *z*, *slong* *len*,  
*slong* *prec*)

void `_acb_poly_polylog_cpx_zeta`(*acb\_ptr* *w*, const *acb\_t* *s*, const *acb\_t* *z*, *slong* *len*,  
*slong* *prec*)

void `_acb_poly_polylog_cpx`(*acb\_ptr* *w*, const *acb\_t* *s*, const *acb\_t* *z*, *slong* *len*, *slong* *prec*)

Sets  $w$  to the Taylor series with respect to  $x$  of the polylogarithm  $\text{Li}_{s+x}(z)$ , where  $s$  and  $z$  are given complex constants. The output is computed to length  $len$  which must be positive. Aliasing between  $w$  and  $s$  or  $z$  is not permitted.

The *small* version uses the standard power series expansion with respect to  $z$ , convergent when  $|z| < 1$ . The *zeta* version evaluates the polylogarithm as a sum of two Hurwitz zeta functions. The default version automatically delegates to the *small* version when  $z$  is close to zero, and the *zeta* version otherwise. For further details, see *Algorithms for polylogarithms*.

void `_acb_poly_polylog_series`(*acb\_ptr* *w*, *acb\_srcptr* *s*, *slong* *slen*, const *acb\_t* *z*, *slong* *len*,  
*slong* *prec*)

void `acb_poly_polylog_series`(*acb\_poly\_t* *w*, const *acb\_poly\_t* *s*, const *acb\_t* *z*, *slong* *len*,  
*slong* *prec*)

Sets  $w$  to the polylogarithm  $\text{Li}_s(z)$  where  $s$  is a given power series, truncating the output to length

*len*. The underscore method requires all lengths to be positive and supports aliasing between all inputs and outputs.

```
void _acb_poly_erf_series(acb_ptr res, acb_srcptr z, slong zlen, slong n, slong prec)
```

```
void acb_poly_erf_series(acb_poly_t res, const acb_poly_t z, slong n, slong prec)
```

Sets *res* to the error function of the power series *z*, truncated to length *n*. These methods are provided for backwards compatibility. See `acb_hypgeom_erf_series()`, `acb_hypgeom_erfc_series()`, `acb_hypgeom_erfi_series()`.

```
void _acb_poly_agm1_series(acb_ptr res, acb_srcptr z, slong zlen, slong len, slong prec)
```

```
void acb_poly_agm1_series(acb_poly_t res, const acb_poly_t z, slong n, slong prec)
```

Sets *res* to the arithmetic-geometric mean of 1 and the power series *z*, truncated to length *n*.

See the `acb_elliptic.h` module for power series of elliptic functions. The following wrappers are available for backwards compatibility.

```
void _acb_poly_elliptic_k_series(acb_ptr res, acb_srcptr z, slong zlen, slong len, slong prec)
```

```
void acb_poly_elliptic_k_series(acb_poly_t res, const acb_poly_t z, slong n, slong prec)
```

```
void _acb_poly_elliptic_p_series(acb_ptr res, acb_srcptr z, slong zlen, const acb_t tau,
                                slong len, slong prec)
```

```
void acb_poly_elliptic_p_series(acb_poly_t res, const acb_poly_t z, const acb_t tau, slong n,
                                slong prec)
```

### 5.2.23 Root-finding

```
void _acb_poly_root_bound_fujiwara(mag_t bound, acb_srcptr poly, slong len)
```

```
void acb_poly_root_bound_fujiwara(mag_t bound, acb_poly_t poly)
```

Sets *bound* to an upper bound for the magnitude of all the complex roots of *poly*. Uses Fujiwara's bound

$$2 \max \left\{ \left| \frac{a_{n-1}}{a_n} \right|, \left| \frac{a_{n-2}}{a_n} \right|^{1/2}, \dots, \left| \frac{a_1}{a_n} \right|^{1/(n-1)}, \left| \frac{a_0}{2a_n} \right|^{1/n} \right\}$$

where  $a_0, \dots, a_n$  are the coefficients of *poly*.

```
void _acb_poly_root_inclusion(acb_t r, const acb_t m, acb_srcptr poly, acb_srcptr polyder,
                             slong len, slong prec)
```

Given any complex number *m*, and a nonconstant polynomial *f* and its derivative *f'*, sets *r* to a complex interval centered on *m* that is guaranteed to contain at least one root of *f*. Such an interval is obtained by taking a ball of radius  $|f(m)/f'(m)|n$  where *n* is the degree of *f*. Proof: assume that the distance to the nearest root exceeds  $r = |f(m)/f'(m)|n$ . Then

$$\left| \frac{f'(m)}{f(m)} \right| = \left| \sum_i \frac{1}{m - \zeta_i} \right| \leq \sum_i \frac{1}{|m - \zeta_i|} < \frac{n}{r} = \left| \frac{f'(m)}{f(m)} \right|$$

which is a contradiction (see [Kob2010]).

```
slong _acb_poly_validate_roots(acb_ptr roots, acb_srcptr poly, slong len, slong prec)
```

Given a list of approximate roots of the input polynomial, this function sets a rigorous bounding interval for each root, and determines which roots are isolated from all the other roots. It then rearranges the list of roots so that the isolated roots are at the front of the list, and returns the count of isolated roots.

If the return value equals the degree of the polynomial, then all roots have been found. If the return value is smaller, all the remaining output intervals are guaranteed to contain roots, but it is possible that not all of the polynomial's roots are contained among them.

```
void _acb_poly_refine_roots_durand_kerner(acb_ptr roots, acb_srcptr poly, slong len,  
                                         slong prec)
```

Refines the given roots simultaneously using a single iteration of the Durand-Kerner method. The radius of each root is set to an approximation of the correction, giving a rough estimate of its error (not a rigorous bound).

```
slong _acb_poly_find_roots(acb_ptr roots, acb_srcptr poly, acb_srcptr initial, slong len,  
                           slong maxiter, slong prec)
```

```
slong acb_poly_find_roots(acb_ptr roots, const acb_poly_t poly, acb_srcptr initial, slong max-  
                           iter, slong prec)
```

Attempts to compute all the roots of the given nonzero polynomial *poly* using a working precision of *prec* bits. If *n* denotes the degree of *poly*, the function writes *n* approximate roots with rigorous error bounds to the preallocated array *roots*, and returns the number of roots that are isolated.

If the return value equals the degree of the polynomial, then all roots have been found. If the return value is smaller, all the output intervals are guaranteed to contain roots, but it is possible that not all of the polynomial's roots are contained among them.

The roots are computed numerically by performing several steps with the Durand-Kerner method and terminating if the estimated accuracy of the roots approaches the working precision or if the number of steps exceeds *maxiter*, which can be set to zero in order to use a default value. Finally, the approximate roots are validated rigorously.

Initial values for the iteration can be provided as the array *initial*. If *initial* is set to *NULL*, default values  $(0.4 + 0.9i)^k$  are used.

The polynomial is assumed to be squarefree. If there are repeated roots, the iteration is likely to find them (with low numerical accuracy), but the error bounds will not converge as the precision increases.

```
int _acb_poly_validate_real_roots(acb_srcptr roots, acb_srcptr poly, slong len, slong prec)
```

```
int acb_poly_validate_real_roots(acb_srcptr roots, const acb_poly_t poly, slong prec)
```

Given a strictly real polynomial *poly* (of length *len*) and isolating intervals for all its complex roots, determines if all the real roots are separated from the non-real roots. If this function returns nonzero, every root enclosure that touches the real axis (as tested by applying *arb\_contains\_zero()* to the imaginary part) corresponds to a real root (its imaginary part can be set to zero), and every other root enclosure corresponds to a non-real root (with known sign for the imaginary part).

If this function returns zero, then the signs of the imaginary parts are not known for certain, based on the accuracy of the inputs and the working precision *prec*.

## 5.3 arb\_fmpz\_poly.h – extra methods for integer polynomials

This module provides methods for FLINT polynomials with integer and rational coefficients (*fmpz\_poly\_t*) and (*fmpq\_poly\_t*) requiring use of Arb real or complex numbers.

Some methods output real or complex numbers while others use real and complex numbers internally to produce an exact result. This module also contains some useful helper functions not specifically related to real and complex numbers.

Note that methods that combine Arb *polynomials* and FLINT polynomials are found in the respective Arb polynomial modules, such as *arb\_poly\_set\_fmpz\_poly()* and *arb\_poly\_get\_unique\_fmpz\_poly()*.

### 5.3.1 Evaluation

```
void _arb_fmpz_poly_evaluate_arb_horner(arb_t res, const fmpz * poly, slong len, const  
                                         arb_t x, slong prec)
```

```
void arb_fmpz_poly_evaluate_arb_horner(arb_t res, const fmpz_poly_t poly, const arb_t x,  
                                         slong prec)
```

```

void _arb_fmpz_poly_evaluate_arb_rectangular(arb_t res, const fmpz * poly, slong len, const
                                             arb_t x, slong prec)
void arb_fmpz_poly_evaluate_arb_rectangular(arb_t res, const fmpz_poly_t poly, const
                                             arb_t x, slong prec)
void _arb_fmpz_poly_evaluate_arb(arb_t res, const fmpz * poly, slong len, const arb_t x,
                                  slong prec)
void arb_fmpz_poly_evaluate_arb(arb_t res, const fmpz_poly_t poly, const arb_t x, slong prec)
void _arb_fmpz_poly_evaluate_acb_horner(acb_t res, const fmpz * poly, slong len, const
                                         acb_t x, slong prec)
void arb_fmpz_poly_evaluate_acb_horner(acb_t res, const fmpz_poly_t poly, const acb_t x,
                                         slong prec)
void _arb_fmpz_poly_evaluate_acb_rectangular(acb_t res, const fmpz * poly, slong len, const
                                              acb_t x, slong prec)
void arb_fmpz_poly_evaluate_acb_rectangular(acb_t res, const fmpz_poly_t poly, const
                                              acb_t x, slong prec)
void _arb_fmpz_poly_evaluate_acb(acb_t res, const fmpz * poly, slong len, const acb_t x,
                                  slong prec)
void arb_fmpz_poly_evaluate_acb(acb_t res, const fmpz_poly_t poly, const acb_t x, slong prec)
    Evaluates poly (given by a polynomial object or an array with len coefficients) at the given real
    or complex number, respectively using Horner's rule, rectangular splitting, or a default algorithm
    choice.

```

### 5.3.2 Utility methods

```

poly)
    Finds the maximal exponent by which poly can be deflated.

void arb_fmpz_poly_deflate(fmpz_poly_t res, const fmpz_poly_t poly, ulong deflation)
    Sets res to a copy of poly deflated by the exponent deflation.

```

### 5.3.3 Polynomial roots

```

void arb_fmpz_poly_complex_roots(acb_ptr roots, const fmpz_poly_t poly, int flags, slong prec)
    Writes to roots all the real and complex roots of the polynomial poly, computed to prec accurate
    bits. The real roots are written first in ascending order (with the imaginary parts set exactly to
    zero). The following nonreal roots are written in arbitrary order, but with conjugate pairs grouped
    together (the root in the upper plane leading the root in the lower plane).

```

The input polynomial *must* be squarefree. For a general polynomial, compute the squarefree part  $f/\gcd(f, f')$  or do a full squarefree factorization to obtain the multiplicities of the roots:

```

fmpz_poly_factor_t fac;
fmpz_poly_factor_init(fac);
fmpz_poly_factor_squarefree(fac, poly);

for (i = 0; i < fac->num; i++)
{
    deg = fmpz_poly_degree(fac->p + i);
    flint_printf("%wd roots of multiplicity %wd\n", deg, fac->exp[i]);
    roots = _acb_vec_init(deg);
    arb_fmpz_poly_complex_roots(roots, fac->p + i, 0, prec);
    _acb_vec_clear(roots, deg);
}

fmpz_poly_factor_clear(fac);

```

All roots are refined to a relative accuracy of at least *prec* bits. The output values will generally have higher actual precision, depending on the precision used internally by the algorithm.

This implementation should be adequate for general use, but it is not currently competitive with state-of-the-art isolation methods for finding real roots alone.

The following *flags* are supported:

- `ARB_FMPZ_POLY_ROOTS_VERBOSE`

### 5.3.4 Special polynomials

Note: see also the methods available in FLINT (e.g. for cyclotomic polynomials).

void `arb_fmpz_poly_cos_minpoly(fmpz_poly_t res, ulong n)`

Sets *res* to the monic minimal polynomial of  $2\cos(2\pi/n)$ . This is a wrapper of FLINT's `fmpz_poly_cos_minpoly`, provided here for backward compatibility.

void `arb_fmpz_poly_gauss_period_minpoly(fmpz_poly_t res, ulong q, ulong n)`

Sets *res* to the minimal polynomial of the Gaussian periods  $\sum_{a \in H} \zeta^a$  where  $\zeta = \exp(2\pi i/q)$  and *H* are the cosets of the subgroups of order  $d = (q-1)/n$  of  $(\mathbb{Z}/q\mathbb{Z})^\times$ . The resulting polynomial has degree *n*. When  $d = 1$ , the result is the cyclotomic polynomial  $\Phi_q$ .

The implementation assumes that *q* is prime, and that *n* is a divisor of  $q-1$  such that *n* is coprime with *d*. If any condition is not met, *res* is set to the zero polynomial.

This method provides a fast (in practice) way to construct finite field extensions of prescribed degree. If *q* satisfies the conditions stated above and  $(q-1)/f$  additionally is coprime with *n*, where *f* is the multiplicative order of *p* mod *q*, then the Gaussian period minimal polynomial is irreducible over  $\text{GF}(p)$  [CP2005].

## MATRICES

These modules implement dense matrices with real and complex coefficients. Rudimentary linear algebra is supported.

### 6.1 `arb_mat.h` – matrices over the real numbers

An `arb_mat_t` represents a dense matrix over the real numbers, implemented as an array of entries of type `arb_struct`.

The dimension (number of rows and columns) of a matrix is fixed at initialization, and the user must ensure that inputs and outputs to an operation have compatible dimensions. The number of rows or columns in a matrix can be zero.

#### 6.1.1 Types, macros and constants

`arb_mat_struct`

`arb_mat_t`

Contains a pointer to a flat array of the entries (`entries`), an array of pointers to the start of each row (`rows`), and the number of rows (`r`) and columns (`c`).

An `arb_mat_t` is defined as an array of length one of type `arb_mat_struct`, permitting an `arb_mat_t` to be passed by reference.

`arb_mat_entry(mat, i, j)`

Macro giving a pointer to the entry at row  $i$  and column  $j$ .

`arb_mat_nrows(mat)`

Returns the number of rows of the matrix.

`arb_mat_ncols(mat)`

Returns the number of columns of the matrix.

#### 6.1.2 Memory management

void `arb_mat_init(arb_mat_t mat, slong r, slong c)`

Initializes the matrix, setting it to the zero matrix with  $r$  rows and  $c$  columns.

void `arb_mat_clear(arb_mat_t mat)`

Clears the matrix, deallocating all entries.

*slong* `arb_mat_allocated_bytes(const arb_mat_t x)`

Returns the total number of bytes heap-allocated internally by this object. The count excludes the size of the structure itself. Add `sizeof(arb_mat_struct)` to get the size of the object as a whole.

### 6.1.3 Conversions

void **arb\_mat\_set**(*arb\_mat\_t* dest, const *arb\_mat\_t* src)

void **arb\_mat\_set\_fmpz\_mat**(*arb\_mat\_t* dest, const *fmpz\_mat\_t* src)

void **arb\_mat\_set\_round\_fmpz\_mat**(*arb\_mat\_t* dest, const *fmpz\_mat\_t* src, *slong* prec)

void **arb\_mat\_set\_fmpq\_mat**(*arb\_mat\_t* dest, const *fmpq\_mat\_t* src, *slong* prec)

Sets *dest* to *src*. The operands must have identical dimensions.

### 6.1.4 Random generation

void **arb\_mat\_randtest**(*arb\_mat\_t* mat, *flint\_rand\_t* state, *slong* prec, *slong* mag\_bits)

Sets *mat* to a random matrix with up to *prec* bits of precision and with exponents of width up to *mag\_bits*.

### 6.1.5 Input and output

void **arb\_mat\_printd**(const *arb\_mat\_t* mat, *slong* digits)

Prints each entry in the matrix with the specified number of decimal digits.

void **arb\_mat\_fprintd**(FILE \* file, const *arb\_mat\_t* mat, *slong* digits)

Prints each entry in the matrix with the specified number of decimal digits to the stream *file*.

### 6.1.6 Comparisons

int **arb\_mat\_equal**(const *arb\_mat\_t* mat1, const *arb\_mat\_t* mat2)

Returns nonzero iff the matrices have the same dimensions and identical entries.

int **arb\_mat\_overlaps**(const *arb\_mat\_t* mat1, const *arb\_mat\_t* mat2)

Returns nonzero iff the matrices have the same dimensions and each entry in *mat1* overlaps with the corresponding entry in *mat2*.

int **arb\_mat\_contains**(const *arb\_mat\_t* mat1, const *arb\_mat\_t* mat2)

int **arb\_mat\_contains\_fmpz\_mat**(const *arb\_mat\_t* mat1, const *fmpz\_mat\_t* mat2)

int **arb\_mat\_contains\_fmpq\_mat**(const *arb\_mat\_t* mat1, const *fmpq\_mat\_t* mat2)

Returns nonzero iff the matrices have the same dimensions and each entry in *mat2* is contained in the corresponding entry in *mat1*.

int **arb\_mat\_eq**(const *arb\_mat\_t* mat1, const *arb\_mat\_t* mat2)

Returns nonzero iff *mat1* and *mat2* certainly represent the same matrix.

int **arb\_mat\_ne**(const *arb\_mat\_t* mat1, const *arb\_mat\_t* mat2)

Returns nonzero iff *mat1* and *mat2* certainly do not represent the same matrix.

int **arb\_mat\_is\_empty**(const *arb\_mat\_t* mat)

Returns nonzero iff the number of rows or the number of columns in *mat* is zero.

int **arb\_mat\_is\_square**(const *arb\_mat\_t* mat)

Returns nonzero iff the number of rows is equal to the number of columns in *mat*.

### 6.1.7 Special matrices

void **arb\_mat\_zero**(*arb\_mat\_t* mat)

Sets all entries in *mat* to zero.

void **arb\_mat\_one**(*arb\_mat\_t* mat)

Sets the entries on the main diagonal to ones, and all other entries to zero.

### 6.1.8 Transpose

void **arb\_mat\_transpose**(*arb\_mat\_t* *dest*, const *arb\_mat\_t* *src*)  
 Sets *dest* to the exact transpose *src*. The operands must have compatible dimensions. Aliasing is allowed.

### 6.1.9 Norms

void **arb\_mat\_bound\_inf\_norm**(*mag\_t* *b*, const *arb\_mat\_t* *A*)  
 Sets *b* to an upper bound for the infinity norm (i.e. the largest absolute value row sum) of *A*.

void **arb\_mat\_frobenius\_norm**(*arb\_t* *res*, const *arb\_mat\_t* *A*, *slong* *prec*)  
 Sets *res* to the Frobenius norm (i.e. the square root of the sum of squares of entries) of *A*.

void **arb\_mat\_bound\_frobenius\_norm**(*mag\_t* *res*, const *arb\_mat\_t* *A*)  
 Sets *res* to an upper bound for the Frobenius norm of *A*.

### 6.1.10 Arithmetic

void **arb\_mat\_neg**(*arb\_mat\_t* *dest*, const *arb\_mat\_t* *src*)  
 Sets *dest* to the exact negation of *src*. The operands must have the same dimensions.

void **arb\_mat\_add**(*arb\_mat\_t* *res*, const *arb\_mat\_t* *mat1*, const *arb\_mat\_t* *mat2*, *slong* *prec*)  
 Sets *res* to the sum of *mat1* and *mat2*. The operands must have the same dimensions.

void **arb\_mat\_sub**(*arb\_mat\_t* *res*, const *arb\_mat\_t* *mat1*, const *arb\_mat\_t* *mat2*, *slong* *prec*)  
 Sets *res* to the difference of *mat1* and *mat2*. The operands must have the same dimensions.

void **arb\_mat\_mul\_classical**(*arb\_mat\_t* *C*, const *arb\_mat\_t* *A*, const *arb\_mat\_t* *B*, *slong* *prec*)  
 void **arb\_mat\_mul\_threaded**(*arb\_mat\_t* *C*, const *arb\_mat\_t* *A*, const *arb\_mat\_t* *B*, *slong* *prec*)  
 void **arb\_mat\_mul**(*arb\_mat\_t* *res*, const *arb\_mat\_t* *mat1*, const *arb\_mat\_t* *mat2*, *slong* *prec*)  
 Sets *res* to the matrix product of *mat1* and *mat2*. The operands must have compatible dimensions for matrix multiplication.

The *threaded* version splits the computation over the number of threads returned by *flint\_get\_num\_threads()*. The default version automatically calls the *threaded* version if the matrices are sufficiently large and more than one thread can be used.

void **arb\_mat\_mul\_entrywise**(*arb\_mat\_t* *C*, const *arb\_mat\_t* *A*, const *arb\_mat\_t* *B*, *slong* *prec*)  
 Sets *C* to the entrywise product of *A* and *B*. The operands must have the same dimensions.

void **arb\_mat\_sqr\_classical**(*arb\_mat\_t* *B*, const *arb\_mat\_t* *A*, *slong* *prec*)  
 void **arb\_mat\_sqr**(*arb\_mat\_t* *res*, const *arb\_mat\_t* *mat*, *slong* *prec*)  
 Sets *res* to the matrix square of *mat*. The operands must both be square with the same dimensions.

void **arb\_mat\_pow\_ui**(*arb\_mat\_t* *res*, const *arb\_mat\_t* *mat*, *ulong* *exp*, *slong* *prec*)  
 Sets *res* to *mat* raised to the power *exp*. Requires that *mat* is a square matrix.

### 6.1.11 Scalar arithmetic

void **arb\_mat\_scalar\_mul\_2exp\_si**(*arb\_mat\_t* *B*, const *arb\_mat\_t* *A*, *slong* *c*)  
 Sets *B* to *A* multiplied by  $2^c$ .

void **arb\_mat\_scalar\_addmul\_si**(*arb\_mat\_t* *B*, const *arb\_mat\_t* *A*, *slong* *c*, *slong* *prec*)  
 void **arb\_mat\_scalar\_addmul\_fmpz**(*arb\_mat\_t* *B*, const *arb\_mat\_t* *A*, const *fmpz\_t* *c*, *slong* *prec*)

```
void arb_mat_scalar_addmul_arb(arb_mat_t B, const arb_mat_t A, const arb_t c, slong prec)
    Sets  $B$  to  $B + A \times c$ .

void arb_mat_scalar_mul_si(arb_mat_t B, const arb_mat_t A, slong c, slong prec)

void arb_mat_scalar_mul_fmpz(arb_mat_t B, const arb_mat_t A, const fmpz_t c, slong prec)

void arb_mat_scalar_mul_arb(arb_mat_t B, const arb_mat_t A, const arb_t c, slong prec)
    Sets  $B$  to  $A \times c$ .

void arb_mat_scalar_div_si(arb_mat_t B, const arb_mat_t A, slong c, slong prec)

void arb_mat_scalar_div_fmpz(arb_mat_t B, const arb_mat_t A, const fmpz_t c, slong prec)

void arb_mat_scalar_div_arb(arb_mat_t B, const arb_mat_t A, const arb_t c, slong prec)
    Sets  $B$  to  $A/c$ .
```

### 6.1.12 Gaussian elimination and solving

```
int arb_mat_lu(slong * perm, arb_mat_t LU, const arb_mat_t A, slong prec)
    Given an  $n \times n$  matrix  $A$ , computes an LU decomposition  $PLU = A$  using Gaussian elimination with
    partial pivoting. The input and output matrices can be the same, performing the decomposition
    in-place.

    Entry  $i$  in the permutation vector perm is set to the row index in the input matrix corresponding
    to row  $i$  in the output matrix.

    The algorithm succeeds and returns nonzero if it can find  $n$  invertible (i.e. not containing zero)
    pivot entries. This guarantees that the matrix is invertible.

    The algorithm fails and returns zero, leaving the entries in  $P$  and  $LU$  undefined, if it cannot find  $n$ 
    invertible pivot elements. In this case, either the matrix is singular, the input matrix was computed
    to insufficient precision, or the LU decomposition was attempted at insufficient precision.

void arb_mat_solve_lu_precomp(arb_mat_t X, const slong * perm, const arb_mat_t LU, const
    arb_mat_t B, slong prec)
    Solves  $AX = B$  given the precomputed nonsingular LU decomposition  $A = PLU$ . The matrices
     $X$  and  $B$  are allowed to be aliased with each other, but  $X$  is not allowed to be aliased with  $LU$ .

int arb_mat_solve(arb_mat_t X, const arb_mat_t A, const arb_mat_t B, slong prec)
    Solves  $AX = B$  where  $A$  is a nonsingular  $n \times n$  matrix and  $X$  and  $B$  are  $n \times m$  matrices, using
    LU decomposition.

    If  $m > 0$  and  $A$  cannot be inverted numerically (indicating either that  $A$  is singular or that the
    precision is insufficient), the values in the output matrix are left undefined and zero is returned. A
    nonzero return value guarantees that  $A$  is invertible and that the exact solution matrix is contained
    in the output.

int arb_mat_inv(arb_mat_t X, const arb_mat_t A, slong prec)
    Sets  $X = A^{-1}$  where  $A$  is a square matrix, computed by solving the system  $AX = I$ .

    If  $A$  cannot be inverted numerically (indicating either that  $A$  is singular or that the precision is
    insufficient), the values in the output matrix are left undefined and zero is returned. A nonzero
    return value guarantees that the matrix is invertible and that the exact inverse is contained in the
    output.

void arb_mat_det(arb_t det, const arb_mat_t A, slong prec)
    Computes the determinant of the matrix, using Gaussian elimination with partial pivoting. If
    at some point an invertible pivot element cannot be found, the elimination is stopped and the
    magnitude of the determinant of the remaining submatrix is bounded using Hadamard's inequality.
```

### 6.1.13 Cholesky decomposition and solving

```
int _arb_mat_cholesky_banachiewicz(arb_mat_t A, slong prec)
```

int **arb\_mat\_cho**(*arb\_mat\_t* L, const *arb\_mat\_t* A, *slong* prec)

Computes the Cholesky decomposition of  $A$ , returning nonzero iff the symmetric matrix defined by the lower triangular part of  $A$  is certainly positive definite.

If a nonzero value is returned, then  $L$  is set to the lower triangular matrix such that  $A = L * L^T$ .

If zero is returned, then either the matrix is not symmetric positive definite, the input matrix was computed to insufficient precision, or the decomposition was attempted at insufficient precision.

The underscore method computes  $L$  from  $A$  in-place, leaving the strict upper triangular region undefined.

void **arb\_mat\_solve\_cho\_precomp**(*arb\_mat\_t* X, const *arb\_mat\_t* L, const *arb\_mat\_t* B, *slong* prec)

Solves  $AX = B$  given the precomputed Cholesky decomposition  $A = LL^T$ . The matrices  $X$  and  $B$  are allowed to be aliased with each other, but  $X$  is not allowed to be aliased with  $L$ .

int **arb\_mat\_spd\_solve**(*arb\_mat\_t* X, const *arb\_mat\_t* A, const *arb\_mat\_t* B, *slong* prec)

Solves  $AX = B$  where  $A$  is a symmetric positive definite matrix and  $X$  and  $B$  are  $n \times m$  matrices, using Cholesky decomposition.

If  $m > 0$  and  $A$  cannot be factored using Cholesky decomposition (indicating either that  $A$  is not symmetric positive definite or that the precision is insufficient), the values in the output matrix are left undefined and zero is returned. A nonzero return value guarantees that the symmetric matrix defined through the lower triangular part of  $A$  is invertible and that the exact solution matrix is contained in the output.

void **arb\_mat\_inv\_cho\_precomp**(*arb\_mat\_t* X, const *arb\_mat\_t* L, *slong* prec)

Sets  $X = A^{-1}$  where  $A$  is a symmetric positive definite matrix whose Cholesky decomposition  $L$  has been computed with **arb\_mat\_cho**( ). The inverse is calculated using the method of [Kri2013] which is more efficient than solving  $AX = I$  with **arb\_mat\_solve\_cho\_precomp**( ).

int **arb\_mat\_spd\_inv**(*arb\_mat\_t* X, const *arb\_mat\_t* A, *slong* prec)

Sets  $X = A^{-1}$  where  $A$  is a symmetric positive definite matrix. It is calculated using the method of [Kri2013] which computes fewer intermediate results than solving  $AX = I$  with **arb\_mat\_spd\_solve**( ).

If  $A$  cannot be factored using Cholesky decomposition (indicating either that  $A$  is not symmetric positive definite or that the precision is insufficient), the values in the output matrix are left undefined and zero is returned. A nonzero return value guarantees that the symmetric matrix defined through the lower triangular part of  $A$  is invertible and that the exact inverse is contained in the output.

int **\_arb\_mat\_ldl\_inplace**(*arb\_mat\_t* A, *slong* prec)

int **\_arb\_mat\_ldl\_golub\_and\_van\_loan**(*arb\_mat\_t* A, *slong* prec)

int **arb\_mat\_ldl**(*arb\_mat\_t* res, const *arb\_mat\_t* A, *slong* prec)

Computes the  $LDL^T$  decomposition of  $A$ , returning nonzero iff the symmetric matrix defined by the lower triangular part of  $A$  is certainly positive definite.

If a nonzero value is returned, then  $res$  is set to a lower triangular matrix that encodes the  $L * D * L^T$  decomposition of  $A$ . In particular,  $L$  is a lower triangular matrix with ones on its diagonal and whose strictly lower triangular region is the same as that of  $res$ .  $D$  is a diagonal matrix with the same diagonal as that of  $res$ .

If zero is returned, then either the matrix is not symmetric positive definite, the input matrix was computed to insufficient precision, or the decomposition was attempted at insufficient precision.

The underscore methods compute  $res$  from  $A$  in-place, leaving the strict upper triangular region undefined. The default method uses algorithm 4.1.2 from [GVL1996].

void **arb\_mat\_solve\_ldl\_precomp**(*arb\_mat\_t* X, const *arb\_mat\_t* L, const *arb\_mat\_t* B, *slong* prec)

Solves  $AX = B$  given the precomputed  $A = LDL^T$  decomposition encoded by  $L$ . The matrices  $X$  and  $B$  are allowed to be aliased with each other, but  $X$  is not allowed to be aliased with  $L$ .

void **arb\_mat\_inv\_ldl\_precomp**(*arb\_mat\_t* X, const *arb\_mat\_t* L, *slong* prec)

Sets  $X = A^{-1}$  where  $A$  is a symmetric positive definite matrix whose  $LDL^T$  decomposition encoded by  $L$  has been computed with `arb_mat_ldl()`. The inverse is calculated using the method of [Kri2013] which is more efficient than solving  $AX = I$  with `arb_mat_solve_ldl_precomp()`.

### 6.1.14 Characteristic polynomial

void **\_arb\_mat\_charpoly**(*arb\_ptr* cp, const *arb\_mat\_t* mat, *slong* prec)

void **arb\_mat\_charpoly**(*arb\_poly\_t* cp, const *arb\_mat\_t* mat, *slong* prec)

Sets  $cp$  to the characteristic polynomial of  $mat$  which must be a square matrix. If the matrix has  $n$  rows, the underscore method requires space for  $n + 1$  output coefficients. Employs a division-free algorithm using  $O(n^4)$  operations.

### 6.1.15 Special functions

void **arb\_mat\_exp\_taylor\_sum**(*arb\_mat\_t* S, const *arb\_mat\_t* A, *slong* N, *slong* prec)

Sets  $S$  to the truncated exponential Taylor series  $S = \sum_{k=0}^{N-1} A^k/k!$ . Uses rectangular splitting to compute the sum using  $O(\sqrt{N})$  matrix multiplications. The recurrence relation for factorials is used to get scalars that are small integers instead of full factorials. As in [Joh2014b], all divisions are postponed to the end by computing partial factorials of length  $O(\sqrt{N})$ . The scalars could be reduced by doing more divisions, but this appears to be slower in most cases.

void **arb\_mat\_exp**(*arb\_mat\_t* B, const *arb\_mat\_t* A, *slong* prec)

Sets  $B$  to the exponential of the matrix  $A$ , defined by the Taylor series

$$\exp(A) = \sum_{k=0}^{\infty} \frac{A^k}{k!}.$$

The function is evaluated as  $\exp(A/2^r)^{2^r}$ , where  $r$  is chosen to give rapid convergence.

The elementwise error when truncating the Taylor series after  $N$  terms is bounded by the error in the infinity norm, for which we have

$$\left\| \exp(2^{-r}A) - \sum_{k=0}^{N-1} \frac{(2^{-r}A)^k}{k!} \right\|_{\infty} = \left\| \sum_{k=N}^{\infty} \frac{(2^{-r}A)^k}{k!} \right\|_{\infty} \leq \sum_{k=N}^{\infty} \frac{(2^{-r}\|A\|_{\infty})^k}{k!}.$$

We bound the sum on the right using `mag_exp_tail()`. Truncation error is not added to entries whose values are determined by the sparsity structure of  $A$ .

void **arb\_mat\_trace**(*arb\_t* trace, const *arb\_mat\_t* mat, *slong* prec)

Sets  $trace$  to the trace of the matrix, i.e. the sum of entries on the main diagonal of  $mat$ . The matrix is required to be square.

### 6.1.16 Sparsity structure

void **arb\_mat\_entrywise\_is\_zero**(*fmpz\_mat\_t* dest, const *arb\_mat\_t* src)

Sets each entry of  $dest$  to indicate whether the corresponding entry of  $src$  is certainly zero. If the entry of  $src$  at row  $i$  and column  $j$  is zero according to `arb_is_zero()` then the entry of  $dest$  at that row and column is set to one, otherwise that entry of  $dest$  is set to zero.

void **arb\_mat\_entrywise\_not\_is\_zero**(*fmpz\_mat\_t* dest, const *arb\_mat\_t* src)

Sets each entry of  $dest$  to indicate whether the corresponding entry of  $src$  is not certainly zero. This is the complement of `arb_mat_entrywise_is_zero()`.

*slong* **arb\_mat\_count\_is\_zero**(const *arb\_mat\_t* mat)

Returns the number of entries of  $mat$  that are certainly zero according to `arb_is_zero()`.

*slong* **arb\_mat\_count\_not\_is\_zero**(const *arb\_mat\_t* mat)

Returns the number of entries of  $mat$  that are not certainly zero.

## 6.2 `acb_mat.h` – matrices over the complex numbers

An `acb_mat_t` represents a dense matrix over the complex numbers, implemented as an array of entries of type `acb_struct`.

The dimension (number of rows and columns) of a matrix is fixed at initialization, and the user must ensure that inputs and outputs to an operation have compatible dimensions. The number of rows or columns in a matrix can be zero.

### 6.2.1 Types, macros and constants

`acb_mat_struct`

`acb_mat_t`

Contains a pointer to a flat array of the entries (`entries`), an array of pointers to the start of each row (`rows`), and the number of rows (`r`) and columns (`c`).

An `acb_mat_t` is defined as an array of length one of type `acb_mat_struct`, permitting an `acb_mat_t` to be passed by reference.

`acb_mat_entry(mat, i, j)`

Macro giving a pointer to the entry at row  $i$  and column  $j$ .

`acb_mat_nrows(mat)`

Returns the number of rows of the matrix.

`acb_mat_ncols(mat)`

Returns the number of columns of the matrix.

### 6.2.2 Memory management

void `acb_mat_init(acb_mat_t mat, slong r, slong c)`

Initializes the matrix, setting it to the zero matrix with  $r$  rows and  $c$  columns.

void `acb_mat_clear(acb_mat_t mat)`

Clears the matrix, deallocating all entries.

*slong* `acb_mat_allocated_bytes(const acb_mat_t x)`

Returns the total number of bytes heap-allocated internally by this object. The count excludes the size of the structure itself. Add `sizeof(acb_mat_struct)` to get the size of the object as a whole.

### 6.2.3 Conversions

void `acb_mat_set(acb_mat_t dest, const acb_mat_t src)`

void `acb_mat_set_fmpz_mat(acb_mat_t dest, const fmpz_mat_t src)`

void `acb_mat_set_round_fmpz_mat(acb_mat_t dest, const fmpz_mat_t src, slong prec)`

void `acb_mat_set_fmpq_mat(acb_mat_t dest, const fmpq_mat_t src, slong prec)`

void `acb_mat_set_arb_mat(acb_mat_t dest, const arb_mat_t src)`

void `acb_mat_set_round_arb_mat(acb_mat_t dest, const arb_mat_t src, slong prec)`

Sets `dest` to `src`. The operands must have identical dimensions.

### 6.2.4 Random generation

void `acb_mat_randtest(acb_mat_t mat, flint_rand_t state, slong prec, slong mag_bits)`

Sets `mat` to a random matrix with up to  $prec$  bits of precision and with exponents of width up to  $mag\_bits$ .

## 6.2.5 Input and output

void **acb\_mat\_printd**(const *acb\_mat\_t* mat, *slong* digits)

Prints each entry in the matrix with the specified number of decimal digits.

void **acb\_mat\_fprintd**(FILE \* file, const *acb\_mat\_t* mat, *slong* digits)

Prints each entry in the matrix with the specified number of decimal digits to the stream *file*.

## 6.2.6 Comparisons

int **acb\_mat\_equal**(const *acb\_mat\_t* mat1, const *acb\_mat\_t* mat2)

Returns nonzero iff the matrices have the same dimensions and identical entries.

int **acb\_mat\_overlaps**(const *acb\_mat\_t* mat1, const *acb\_mat\_t* mat2)

Returns nonzero iff the matrices have the same dimensions and each entry in *mat1* overlaps with the corresponding entry in *mat2*.

int **acb\_mat\_contains**(const *acb\_mat\_t* mat1, const *acb\_mat\_t* mat2)

int **acb\_mat\_contains\_fmpz\_mat**(const *acb\_mat\_t* mat1, const *fmpz\_mat\_t* mat2)

int **acb\_mat\_contains\_fmpq\_mat**(const *acb\_mat\_t* mat1, const *fmpq\_mat\_t* mat2)

Returns nonzero iff the matrices have the same dimensions and each entry in *mat2* is contained in the corresponding entry in *mat1*.

int **acb\_mat\_eq**(const *acb\_mat\_t* mat1, const *acb\_mat\_t* mat2)

Returns nonzero iff *mat1* and *mat2* certainly represent the same matrix.

int **acb\_mat\_ne**(const *acb\_mat\_t* mat1, const *acb\_mat\_t* mat2)

Returns nonzero iff *mat1* and *mat2* certainly do not represent the same matrix.

int **acb\_mat\_is\_real**(const *acb\_mat\_t* mat)

Returns nonzero iff all entries in *mat* have zero imaginary part.

int **acb\_mat\_is\_empty**(const *acb\_mat\_t* mat)

Returns nonzero iff the number of rows or the number of columns in *mat* is zero.

int **acb\_mat\_is\_square**(const *acb\_mat\_t* mat)

Returns nonzero iff the number of rows is equal to the number of columns in *mat*.

## 6.2.7 Special matrices

void **acb\_mat\_zero**(*acb\_mat\_t* mat)

Sets all entries in *mat* to zero.

void **acb\_mat\_one**(*acb\_mat\_t* mat)

Sets the entries on the main diagonal to ones, and all other entries to zero.

## 6.2.8 Transpose

void **acb\_mat\_transpose**(*acb\_mat\_t* dest, const *acb\_mat\_t* src)

Sets *dest* to the exact transpose *src*. The operands must have compatible dimensions. Aliasing is allowed.

## 6.2.9 Norms

void **acb\_mat\_bound\_inf\_norm**(*mag\_t* b, const *acb\_mat\_t* A)

Sets *b* to an upper bound for the infinity norm (i.e. the largest absolute value row sum) of *A*.

void **acb\_mat\_frobenius\_norm**(*acb\_t* res, const *acb\_mat\_t* A, *slong* prec)

Sets *res* to the Frobenius norm (i.e. the square root of the sum of squares of entries) of *A*.

void **acb\_mat\_bound\_frobenius\_norm**(*mag\_t* res, const *acb\_mat\_t* A)  
 Sets *res* to an upper bound for the Frobenius norm of *A*.

## 6.2.10 Arithmetic

void **acb\_mat\_neg**(*acb\_mat\_t* dest, const *acb\_mat\_t* src)  
 Sets *dest* to the exact negation of *src*. The operands must have the same dimensions.

void **acb\_mat\_add**(*acb\_mat\_t* res, const *acb\_mat\_t* mat1, const *acb\_mat\_t* mat2, *slong prec*)  
 Sets *res* to the sum of *mat1* and *mat2*. The operands must have the same dimensions.

void **acb\_mat\_sub**(*acb\_mat\_t* res, const *acb\_mat\_t* mat1, const *acb\_mat\_t* mat2, *slong prec*)  
 Sets *res* to the difference of *mat1* and *mat2*. The operands must have the same dimensions.

void **acb\_mat\_mul**(*acb\_mat\_t* res, const *acb\_mat\_t* mat1, const *acb\_mat\_t* mat2, *slong prec*)  
 Sets *res* to the matrix product of *mat1* and *mat2*. The operands must have compatible dimensions for matrix multiplication.

void **acb\_mat\_mul\_entrywise**(*acb\_mat\_t* res, const *acb\_mat\_t* mat1, const *acb\_mat\_t* mat2, *slong prec*)  
 Sets *res* to the entrywise product of *mat1* and *mat2*. The operands must have the same dimensions.

void **acb\_mat\_sqr**(*acb\_mat\_t* res, const *acb\_mat\_t* mat, *slong prec*)  
 Sets *res* to the matrix square of *mat*. The operands must both be square with the same dimensions.

void **acb\_mat\_pow\_ui**(*acb\_mat\_t* res, const *acb\_mat\_t* mat, *ulong exp*, *slong prec*)  
 Sets *res* to *mat* raised to the power *exp*. Requires that *mat* is a square matrix.

## 6.2.11 Scalar arithmetic

void **acb\_mat\_scalar\_mul\_2exp\_si**(*acb\_mat\_t* B, const *acb\_mat\_t* A, *slong c*)  
 Sets *B* to *A* multiplied by  $2^c$ .

void **acb\_mat\_scalar\_addmul\_si**(*acb\_mat\_t* B, const *acb\_mat\_t* A, *slong c*, *slong prec*)

void **acb\_mat\_scalar\_addmul\_fmpz**(*acb\_mat\_t* B, const *acb\_mat\_t* A, const *fmpz\_t* c, *slong prec*)

void **acb\_mat\_scalar\_addmul\_arb**(*acb\_mat\_t* B, const *acb\_mat\_t* A, const *arb\_t* c, *slong prec*)

void **acb\_mat\_scalar\_addmul\_acb**(*acb\_mat\_t* B, const *acb\_mat\_t* A, const *acb\_t* c, *slong prec*)  
 Sets *B* to  $B + A \times c$ .

void **acb\_mat\_scalar\_mul\_si**(*acb\_mat\_t* B, const *acb\_mat\_t* A, *slong c*, *slong prec*)

void **acb\_mat\_scalar\_mul\_fmpz**(*acb\_mat\_t* B, const *acb\_mat\_t* A, const *fmpz\_t* c, *slong prec*)

void **acb\_mat\_scalar\_mul\_arb**(*acb\_mat\_t* B, const *acb\_mat\_t* A, const *arb\_t* c, *slong prec*)

void **acb\_mat\_scalar\_mul\_acb**(*acb\_mat\_t* B, const *acb\_mat\_t* A, const *acb\_t* c, *slong prec*)  
 Sets *B* to  $A \times c$ .

void **acb\_mat\_scalar\_div\_si**(*acb\_mat\_t* B, const *acb\_mat\_t* A, *slong c*, *slong prec*)

void **acb\_mat\_scalar\_div\_fmpz**(*acb\_mat\_t* B, const *acb\_mat\_t* A, const *fmpz\_t* c, *slong prec*)

void **acb\_mat\_scalar\_div\_arb**(*acb\_mat\_t* B, const *acb\_mat\_t* A, const *arb\_t* c, *slong prec*)

void **acb\_mat\_scalar\_div\_acb**(*acb\_mat\_t* B, const *acb\_mat\_t* A, const *acb\_t* c, *slong prec*)  
 Sets *B* to  $A/c$ .

## 6.2.12 Gaussian elimination and solving

int **acb\_mat\_lu**(*slong* \* perm, *acb\_mat\_t* LU, const *acb\_mat\_t* A, *slong* prec)

Given an  $n \times n$  matrix  $A$ , computes an LU decomposition  $PLU = A$  using Gaussian elimination with partial pivoting. The input and output matrices can be the same, performing the decomposition in-place.

Entry  $i$  in the permutation vector *perm* is set to the row index in the input matrix corresponding to row  $i$  in the output matrix.

The algorithm succeeds and returns nonzero if it can find  $n$  invertible (i.e. not containing zero) pivot entries. This guarantees that the matrix is invertible.

The algorithm fails and returns zero, leaving the entries in  $P$  and  $LU$  undefined, if it cannot find  $n$  invertible pivot elements. In this case, either the matrix is singular, the input matrix was computed to insufficient precision, or the LU decomposition was attempted at insufficient precision.

void **acb\_mat\_solve\_lu\_precomp**(*acb\_mat\_t* X, const *slong* \* perm, const *acb\_mat\_t* LU, const *acb\_mat\_t* B, *slong* prec)

Solves  $AX = B$  given the precomputed nonsingular LU decomposition  $A = PLU$ . The matrices  $X$  and  $B$  are allowed to be aliased with each other, but  $X$  is not allowed to be aliased with  $LU$ .

int **acb\_mat\_solve**(*acb\_mat\_t* X, const *acb\_mat\_t* A, const *acb\_mat\_t* B, *slong* prec)

Solves  $AX = B$  where  $A$  is a nonsingular  $n \times n$  matrix and  $X$  and  $B$  are  $n \times m$  matrices, using LU decomposition.

If  $m > 0$  and  $A$  cannot be inverted numerically (indicating either that  $A$  is singular or that the precision is insufficient), the values in the output matrix are left undefined and zero is returned. A nonzero return value guarantees that  $A$  is invertible and that the exact solution matrix is contained in the output.

int **acb\_mat\_inv**(*acb\_mat\_t* X, const *acb\_mat\_t* A, *slong* prec)

Sets  $X = A^{-1}$  where  $A$  is a square matrix, computed by solving the system  $AX = I$ .

If  $A$  cannot be inverted numerically (indicating either that  $A$  is singular or that the precision is insufficient), the values in the output matrix are left undefined and zero is returned. A nonzero return value guarantees that the matrix is invertible and that the exact inverse is contained in the output.

void **acb\_mat\_det**(*acb\_t* det, const *acb\_mat\_t* A, *slong* prec)

Computes the determinant of the matrix, using Gaussian elimination with partial pivoting. If at some point an invertible pivot element cannot be found, the elimination is stopped and the magnitude of the determinant of the remaining submatrix is bounded using Hadamard's inequality.

## 6.2.13 Characteristic polynomial

void **\_acb\_mat\_charpoly**(*acb\_ptr* cp, const *acb\_mat\_t* mat, *slong* prec)

void **acb\_mat\_charpoly**(*acb\_poly\_t* cp, const *acb\_mat\_t* mat, *slong* prec)

Sets *cp* to the characteristic polynomial of *mat* which must be a square matrix. If the matrix has  $n$  rows, the underscore method requires space for  $n + 1$  output coefficients. Employs a division-free algorithm using  $O(n^4)$  operations.

## 6.2.14 Special functions

void **acb\_mat\_exp\_taylor\_sum**(*acb\_mat\_t* S, const *acb\_mat\_t* A, *slong* N, *slong* prec)

Sets  $S$  to the truncated exponential Taylor series  $S = \sum_{k=0}^{N-1} A^k/k!$ . See *arb\_mat\_exp\_taylor\_sum()* for implementation notes.

void **acb\_mat\_exp**(*acb\_mat\_t* *B*, const *acb\_mat\_t* *A*, *slong* *prec*)

Sets *B* to the exponential of the matrix *A*, defined by the Taylor series

$$\exp(A) = \sum_{k=0}^{\infty} \frac{A^k}{k!}.$$

The function is evaluated as  $\exp(A/2^r)^{2^r}$ , where *r* is chosen to give rapid convergence of the Taylor series. Error bounds are computed as for *arb\_mat\_exp()*.

void **acb\_mat\_trace**(*acb\_t* *trace*, const *acb\_mat\_t* *mat*, *slong* *prec*)

Sets *trace* to the trace of the matrix, i.e. the sum of entries on the main diagonal of *mat*. The matrix is required to be square.

## HIGHER MATHEMATICAL FUNCTIONS

These modules implement mathematical functions with complexity that goes beyond the basics covered directly in the *arb* and *acb* modules.

### 7.1 *acb\_hypgeom.h* – hypergeometric functions of complex variables

The generalized hypergeometric function is formally defined by

$${}_pF_q(a_1, \dots, a_p; b_1, \dots, b_q; z) = \sum_{k=0}^{\infty} \frac{(a_1)_k \dots (a_p)_k}{(b_1)_k \dots (b_q)_k} \frac{z^k}{k!}.$$

It can be interpreted using analytic continuation or regularization when the sum does not converge. In a looser sense, we understand “hypergeometric functions” to be linear combinations of generalized hypergeometric functions with prefactors that are products of exponentials, powers, and gamma functions.

#### 7.1.1 Convergent series

In this section, we define

$$T(k) = \frac{\prod_{i=0}^{p-1} (a_i)_k}{\prod_{i=0}^{q-1} (b_i)_k} z^k$$

and

$${}_p f_q(a_0, \dots, a_{p-1}; b_0 \dots b_{q-1}; z) = {}_{p+1}F_q(a_0, \dots, a_{p-1}, 1; b_0 \dots b_{q-1}; z) = \sum_{k=0}^{\infty} T(k)$$

For the conventional generalized hypergeometric function  ${}_pF_q$ , compute  ${}_p f_{q+1}$  with the explicit parameter  $b_q = 1$ , or remove a 1 from the  $a_i$  parameters if there is one.

`void acb_hypgeom_pfq_bound_factor(mag_t C, acb_srcptr a, slong p, acb_srcptr b, slong q, const acb_t z, ulong n)`

Computes a factor  $C$  such that  $|\sum_{k=n}^{\infty} T(k)| \leq C|T(n)|$ . See *Convergent series*. As currently implemented, the bound becomes infinite when  $n$  is too small, even if the series converges.

`slong acb_hypgeom_pfq_choose_n(acb_srcptr a, slong p, acb_srcptr b, slong q, const acb_t z, slong prec)`

Heuristically attempts to choose a number of terms  $n$  to sum of a hypergeometric series at a working precision of  $prec$  bits.

Uses double precision arithmetic internally. As currently implemented, it can fail to produce a good result if the parameters are extremely large or extremely close to nonpositive integers.

Numerical cancellation is assumed to be significant, so truncation is done when the current term is  $prec$  bits smaller than the largest encountered term.

This function will also attempt to pick a reasonable truncation point for divergent series.

```
void acb_hypgeom_pfq_sum_forward(acb_t s, acb_t t, acb_srcptr a, slong p, acb_srcptr b,
                                slong q, const acb_t z, slong n, slong prec)
```

```
void acb_hypgeom_pfq_sum_rs(acb_t s, acb_t t, acb_srcptr a, slong p, acb_srcptr b, slong q,
                             const acb_t z, slong n, slong prec)
```

```
void acb_hypgeom_pfq_sum_bs(acb_t s, acb_t t, acb_srcptr a, slong p, acb_srcptr b, slong q,
                             const acb_t z, slong n, slong prec)
```

```
void acb_hypgeom_pfq_sum_fme(acb_t s, acb_t t, acb_srcptr a, slong p, acb_srcptr b, slong q,
                              const acb_t z, slong n, slong prec)
```

```
void acb_hypgeom_pfq_sum(acb_t s, acb_t t, acb_srcptr a, slong p, acb_srcptr b, slong q, const
                          acb_t z, slong n, slong prec)
```

Computes  $s = \sum_{k=0}^{n-1} T(k)$  and  $t = T(n)$ . Does not allow aliasing between input and output variables. We require  $n \geq 0$ .

The *forward* version computes the sum using forward recurrence.

The *bs* version computes the sum using binary splitting.

The *rs* version computes the sum in reverse order using rectangular splitting. It only computes a magnitude bound for the value of  $t$ .

The *fme* version uses fast multipoint evaluation.

The default version automatically chooses an algorithm depending on the inputs.

```
void acb_hypgeom_pfq_sum_bs_invz(acb_t s, acb_t t, acb_srcptr a, slong p, acb_srcptr b,
                                 slong q, const acb_t w, slong n, slong prec)
```

```
void acb_hypgeom_pfq_sum_invz(acb_t s, acb_t t, acb_srcptr a, slong p, acb_srcptr b, slong q,
                              const acb_t z, const acb_t w, slong n, slong prec)
```

Like `acb_hypgeom_pfq_sum()`, but taking advantage of  $w = 1/z$  possibly having few bits.

```
void acb_hypgeom_pfq_direct(acb_t res, acb_srcptr a, slong p, acb_srcptr b, slong q, const
                            acb_t z, slong n, slong prec)
```

Computes

$${}_pf_q(z) = \sum_{k=0}^{\infty} T(k) = \sum_{k=0}^{n-1} T(k) + \varepsilon$$

directly from the defining series, including a rigorous bound for the truncation error  $\varepsilon$  in the output.

If  $n < 0$ , this function chooses a number of terms automatically using `acb_hypgeom_pfq_choose_n()`.

```
void acb_hypgeom_pfq_series_sum_forward(acb_poly_t s, acb_poly_t t, const acb_poly_struct
                                         * a, slong p, const acb_poly_struct * b, slong q,
                                         const acb_poly_t z, int regularized, slong n,
                                         slong len, slong prec)
```

```
void acb_hypgeom_pfq_series_sum_bs(acb_poly_t s, acb_poly_t t, const acb_poly_struct
                                    * a, slong p, const acb_poly_struct * b, slong q,
                                    const acb_poly_t z, int regularized, slong n, slong len,
                                    slong prec)
```

```
void acb_hypgeom_pfq_series_sum_rs(acb_poly_t s, acb_poly_t t, const acb_poly_struct
                                    * a, slong p, const acb_poly_struct * b, slong q,
                                    const acb_poly_t z, int regularized, slong n, slong len,
                                    slong prec)
```

```
void acb_hypgeom_pfq_series_sum(acb_poly_t s, acb_poly_t t, const acb_poly_struct * a,
                                 slong p, const acb_poly_struct * b, slong q, const
                                 acb_poly_t z, int regularized, slong n, slong len, slong prec)
```

Computes  $s = \sum_{k=0}^{n-1} T(k)$  and  $t = T(n)$  given parameters and argument that are power series. Does not allow aliasing between input and output variables. We require  $n \geq 0$  and that *len* is positive.

If *regularized* is set, the regularized sum is computed, avoiding division by zero at the poles of the gamma function.

The *forward*, *bs*, *rs* and default versions use forward recurrence, binary splitting, rectangular splitting, and an automatic algorithm choice.

```
void acb_hypgeom_pfq_series_direct(acb_poly_t res, const acb_poly_struct * a, slong p, const
                                acb_poly_struct * b, slong q, const acb_poly_t z, int reg-
                                ularized, slong n, slong len, slong prec)
```

Computes  ${}_pF_q(z)$  directly using the defining series, given parameters and argument that are power series. The result is a power series of length *len*. We require that *len* is positive.

An error bound is computed automatically as a function of the number of terms *n*. If *n* < 0, the number of terms is chosen automatically.

If *regularized* is set, the regularized hypergeometric function is computed instead.

## 7.1.2 Asymptotic series

$U(a, b, z)$  is the confluent hypergeometric function of the second kind with the principal branch cut, and  $U^* = z^a U(a, b, z)$ . For details about how error bounds are computed, see [Asymptotic series for the confluent hypergeometric function](#).

```
void acb_hypgeom_u_asymp(acb_t res, const acb_t a, const acb_t b, const acb_t z, slong n,
                        slong prec)
```

Sets *res* to  $U^*(a, b, z)$  computed using *n* terms of the asymptotic series, with a rigorous bound for the error included in the output. We require *n* ≥ 0.

```
int acb_hypgeom_u_use_asymp(const acb_t z, slong prec)
```

Heuristically determines whether the asymptotic series can be used to evaluate  $U(a, b, z)$  to *prec* accurate bits (assuming that *a* and *b* are small).

## 7.1.3 Generalized hypergeometric function

```
void acb_hypgeom_pfq(acb_poly_t res, acb_srcptr a, slong p, acb_srcptr b, slong q, const acb_t z,
                    int regularized, slong prec)
```

Computes the generalized hypergeometric function  ${}_pF_q(z)$ , or the regularized version if *regularized* is set.

This function automatically delegates to a specialized implementation when the order (*p*, *q*) is one of (0,0), (1,0), (0,1), (1,1), (2,1). Otherwise, it falls back to direct summation.

While this is a top-level function meant to take care of special cases automatically, it does not generally perform the optimization of deleting parameters that appear in both *a* and *b*. This can be done ahead of time by the user in applications where duplicate parameters are likely to occur.

## 7.1.4 Confluent hypergeometric functions

```
void acb_hypgeom_u_1f1_series(acb_poly_t res, const acb_poly_t a, const acb_poly_t b, const
                             acb_poly_t z, slong len, slong prec)
```

Computes  $U(a, b, z)$  as a power series truncated to length *len*, given  $a, b, z \in \mathbb{C}[[x]]$ . If  $b[0] \in \mathbb{Z}$ , it computes one extra derivative and removes the singularity (it is then assumed that  $b[1] \neq 0$ ). As currently implemented, the output is indeterminate if *b* is nonexact and contains an integer.

```
void acb_hypgeom_u_1f1(acb_t res, const acb_t a, const acb_t b, const acb_t z, slong prec)
```

Computes  $U(a, b, z)$  as a sum of two convergent hypergeometric series. If  $b \in \mathbb{Z}$ , it computes the limit value via `acb_hypgeom_u_1f1_series()`. As currently implemented, the output is indeterminate if *b* is nonexact and contains an integer.

void **acb\_hypgeom\_u**(*acb\_t* res, const *acb\_t* a, const *acb\_t* b, const *acb\_t* z, *slong* prec)  
 Computes  $U(a, b, z)$  using an automatic algorithm choice. The function **acb\_hypgeom\_u\_asymp**() is used if  $a$  or  $a - b + 1$  is a nonpositive integer (in which case the asymptotic series terminates), or if  $z$  is sufficiently large. Otherwise **acb\_hypgeom\_u\_1f1**() is used.

void **acb\_hypgeom\_m\_asymp**(*acb\_t* res, const *acb\_t* a, const *acb\_t* b, const *acb\_t* z, int *regularized*, *slong* prec)  
 void **acb\_hypgeom\_m\_1f1**(*acb\_t* res, const *acb\_t* a, const *acb\_t* b, const *acb\_t* z, int *regularized*, *slong* prec)  
 void **acb\_hypgeom\_m**(*acb\_t* res, const *acb\_t* a, const *acb\_t* b, const *acb\_t* z, int *regularized*, *slong* prec)  
 Computes the confluent hypergeometric function  $M(a, b, z) = {}_1F_1(a, b, z)$ , or  $\mathbf{M}(a, b, z) = \frac{1}{\Gamma(b)} {}_1F_1(a, b, z)$  if *regularized* is set.

void **acb\_hypgeom\_1f1**(*acb\_t* res, const *acb\_t* a, const *acb\_t* b, const *acb\_t* z, int *regularized*, *slong* prec)  
 Alias for **acb\_hypgeom\_m**() .

void **acb\_hypgeom\_0f1\_asymp**(*acb\_t* res, const *acb\_t* a, const *acb\_t* z, int *regularized*, *slong* prec)  
 void **acb\_hypgeom\_0f1\_direct**(*acb\_t* res, const *acb\_t* a, const *acb\_t* z, int *regularized*, *slong* prec)  
 void **acb\_hypgeom\_0f1**(*acb\_t* res, const *acb\_t* a, const *acb\_t* z, int *regularized*, *slong* prec)  
 Computes the confluent hypergeometric function  ${}_0F_1(a, z)$ , or  $\frac{1}{\Gamma(a)} {}_0F_1(a, z)$  if *regularized* is set, using asymptotic expansions, direct summation, or an automatic algorithm choice. The *asymp* version uses the asymptotic expansions of Bessel functions, together with the connection formulas

$$\frac{{}_0F_1(a, z)}{\Gamma(a)} = (-z)^{(1-a)/2} J_{a-1}(2\sqrt{-z}) = z^{(1-a)/2} I_{a-1}(2\sqrt{z}).$$

The Bessel- $J$  function is used in the left half-plane and the Bessel- $I$  function is used in the right half-plane, to avoid loss of accuracy due to evaluating the square root on the branch cut.

## 7.1.5 Error functions and Fresnel integrals

void **acb\_hypgeom\_erf\_propagated\_error**(*mag\_t* re, *mag\_t* im, const *acb\_t* z)  
 Sets *re* and *im* to upper bounds for the error in the real and imaginary part resulting from approximating the error function of  $z$  by the error function evaluated at the midpoint of  $z$ . Uses the first derivative.

void **acb\_hypgeom\_erf\_1f1a**(*acb\_t* res, const *acb\_t* z, *slong* prec)  
 void **acb\_hypgeom\_erf\_1f1b**(*acb\_t* res, const *acb\_t* z, *slong* prec)  
 void **acb\_hypgeom\_erf\_asymp**(*acb\_t* res, const *acb\_t* z, int *complementary*, *slong* prec, *slong* prec2)  
 Computes the error function respectively using

$$\begin{aligned} \operatorname{erf}(z) &= \frac{2z}{\sqrt{\pi}} {}_1F_1\left(\frac{1}{2}, \frac{3}{2}, -z^2\right) \\ \operatorname{erf}(z) &= \frac{2ze^{-z^2}}{\sqrt{\pi}} {}_1F_1\left(1, \frac{3}{2}, z^2\right) \\ \operatorname{erf}(z) &= \frac{z}{\sqrt{z^2}} \left(1 - \frac{e^{-z^2}}{\sqrt{\pi}} U\left(\frac{1}{2}, \frac{1}{2}, z^2\right)\right) = \frac{z}{\sqrt{z^2}} - \frac{e^{-z^2}}{z\sqrt{\pi}} U^*\left(\frac{1}{2}, \frac{1}{2}, z^2\right). \end{aligned}$$

The *asymp* version takes a second precision to use for the  $U$  term. It also takes an extra flag *complementary*, computing the complementary error function if set.

void **acb\_hypgeom\_erf**(*acb\_t* res, const *acb\_t* z, *slong* prec)  
 Computes the error function using an automatic algorithm choice. If  $z$  is too small to use the

asymptotic expansion, a working precision sufficient to circumvent cancellation in the hypergeometric series is determined automatically, and a bound for the propagated error is computed with `acb_hypgeom_erf_propagated_error()`.

```
void _acb_hypgeom_erf_series(acb_ptr res, acb_srcptr z, slong zlen, slong len, slong prec)
void acb_hypgeom_erf_series(acb_poly_t res, const acb_poly_t z, slong len, slong prec)
    Computes the error function of the power series z, truncated to length len.

void acb_hypgeom_erfc(acb_t res, const acb_t z, slong prec)
    Computes the complementary error function  $\operatorname{erfc}(z) = 1 - \operatorname{erf}(z)$ . This function avoids catastrophic
    cancellation for large positive z.

void _acb_hypgeom_erfc_series(acb_ptr res, acb_srcptr z, slong zlen, slong len, slong prec)
void acb_hypgeom_erfc_series(acb_poly_t res, const acb_poly_t z, slong len, slong prec)
    Computes the complementary error function of the power series z, truncated to length len.

void acb_hypgeom_erfi(acb_t res, const acb_t z, slong prec)
    Computes the imaginary error function  $\operatorname{erfi}(z) = -i \operatorname{erf}(iz)$ . This is a trivial wrapper of
    acb_hypgeom_erf().

void _acb_hypgeom_erfi_series(acb_ptr res, acb_srcptr z, slong zlen, slong len, slong prec)
void acb_hypgeom_erfi_series(acb_poly_t res, const acb_poly_t z, slong len, slong prec)
    Computes the imaginary error function of the power series z, truncated to length len.

void acb_hypgeom_fresnel(acb_t res1, acb_t res2, const acb_t z, int normalized, slong prec)
    Sets res1 to the Fresnel sine integral  $S(z)$  and res2 to the Fresnel cosine integral  $C(z)$ . Optionally,
    just a single function can be computed by passing NULL as the other output variable. The definition
 $S(z) = \int_0^z \sin(t^2) dt$  is used if normalized is 0, and  $S(z) = \int_0^z \sin(\frac{1}{2}\pi t^2) dt$  is used if normalized is 1
    (the latter is the Abramowitz & Stegun convention).  $C(z)$  is defined analogously.

void _acb_hypgeom_fresnel_series(acb_ptr res1, acb_ptr res2, acb_srcptr z, slong zlen,
    int normalized, slong len, slong prec)
void acb_hypgeom_fresnel_series(acb_poly_t res1, acb_poly_t res2, const acb_poly_t z,
    int normalized, slong len, slong prec)
    Sets res1 to the Fresnel sine integral and res2 to the Fresnel cosine integral of the power series z,
    truncated to length len. Optionally, just a single function can be computed by passing NULL as
    the other output variable.
```

### 7.1.6 Bessel functions

```
void acb_hypgeom_bessel_j_asymp(acb_t res, const acb_t nu, const acb_t z, slong prec)
    Computes the Bessel function of the first kind via acb_hypgeom_u_asymp(). For all complex  $\nu, z$ ,
    we have
```

$$J_\nu(z) = \frac{z^\nu}{2^\nu e^{iz} \Gamma(\nu+1)} {}_1F_1\left(\nu + \frac{1}{2}, 2\nu + 1, 2iz\right) = A_+ B_+ + A_- B_-$$

where

$$A_\pm = z^\nu (z^2)^{-\frac{1}{2}-\nu} (\mp iz)^{\frac{1}{2}+\nu} (2\pi)^{-1/2} = (\pm iz)^{-1/2-\nu} z^\nu (2\pi)^{-1/2}$$

$$B_\pm = e^{\pm iz} U^*(\nu + \frac{1}{2}, 2\nu + 1, \mp 2iz).$$

Nicer representations of the factors  $A_\pm$  can be given depending conditionally on the parameters. If  $\nu + \frac{1}{2} = n \in \mathbb{Z}$ , we have  $A_\pm = (\pm i)^n (2\pi z)^{-1/2}$ . And if  $\operatorname{Re}(z) > 0$ , we have  $A_\pm = \exp(\mp i[(2\nu + 1)/4]\pi) (2\pi z)^{-1/2}$ .

```
void acb_hypgeom_bessel_j_0f1(acb_t res, const acb_t nu, const acb_t z, slong prec)
    Computes the Bessel function of the first kind from
```

$$J_\nu(z) = \frac{1}{\Gamma(\nu+1)} \left(\frac{z}{2}\right)^\nu {}_0F_1\left(\nu+1, -\frac{z^2}{4}\right).$$

void **acb\_hypgeom\_bessel\_j**(*acb\_t res*, const *acb\_t nu*, const *acb\_t z*, *slong prec*)

Computes the Bessel function of the first kind  $J_\nu(z)$  using an automatic algorithm choice.

void **acb\_hypgeom\_bessel\_y**(*acb\_t res*, const *acb\_t nu*, const *acb\_t z*, *slong prec*)

Computes the Bessel function of the second kind  $Y_\nu(z)$  from the formula

$$Y_\nu(z) = \frac{\cos(\nu\pi)J_\nu(z) - J_{-\nu}(z)}{\sin(\nu\pi)}$$

unless  $\nu = n$  is an integer in which case the limit value

$$Y_n(z) = -\frac{2}{\pi} (i^n K_n(iz) + [\log(iz) - \log(z)] J_n(z))$$

is computed. As currently implemented, the output is indeterminate if  $\nu$  is nonexact and contains an integer.

void **acb\_hypgeom\_bessel\_jy**(*acb\_t res1*, *acb\_t res2*, const *acb\_t nu*, const *acb\_t z*, *slong prec*)

Sets *res1* to  $J_\nu(z)$  and *res2* to  $Y_\nu(z)$ , computed simultaneously. From these values, the user can easily construct the Bessel functions of the third kind (Hankel functions)  $H_\nu^{(1)}(z)$ ,  $H_\nu^{(2)}(z) = J_\nu(z) \pm iY_\nu(z)$ .

void **acb\_hypgeom\_bessel\_i\_asymp**(*acb\_t res*, const *acb\_t nu*, const *acb\_t z*, *slong prec*)

void **acb\_hypgeom\_bessel\_i\_of1**(*acb\_t res*, const *acb\_t nu*, const *acb\_t z*, *slong prec*)

void **acb\_hypgeom\_bessel\_i**(*acb\_t res*, const *acb\_t nu*, const *acb\_t z*, *slong prec*)

Computes the modified Bessel function of the first kind  $I_\nu(z) = z^\nu(iz)^{-\nu}J_\nu(iz)$  respectively using asymptotic series (see **acb\_hypgeom\_bessel\_j\_asymp()**), the convergent series

$$I_\nu(z) = \frac{1}{\Gamma(\nu+1)} \left(\frac{z}{2}\right)^\nu {}_0F_1\left(\nu+1, \frac{z^2}{4}\right),$$

or an automatic algorithm choice.

void **acb\_hypgeom\_bessel\_k\_asymp**(*acb\_t res*, const *acb\_t nu*, const *acb\_t z*, *slong prec*)

Computes the modified Bessel function of the second kind via **acb\_hypgeom\_u\_asymp()**. For all  $\nu$  and all  $z \neq 0$ , we have

$$K_\nu(z) = \left(\frac{2z}{\pi}\right)^{-1/2} e^{-z} U^*\left(\nu + \frac{1}{2}, 2\nu + 1, 2z\right).$$

void **acb\_hypgeom\_bessel\_k\_of1\_series**(*acb\_poly\_t res*, const *acb\_poly\_t nu*, const *acb\_poly\_t z*, *slong len*, *slong prec*)

Computes the modified Bessel function of the second kind  $K_\nu(z)$  as a power series truncated to length *len*, given  $\nu, z \in \mathbb{C}[[x]]$ . Uses the formula

$$K_\nu(z) = \frac{1}{2} \frac{\pi}{\sin(\pi\nu)} \left[ \left(\frac{z}{2}\right)^{-\nu} {}_0\tilde{F}_1\left(1-\nu, \frac{z^2}{4}\right) - \left(\frac{z}{2}\right)^\nu {}_0\tilde{F}_1\left(1+\nu, \frac{z^2}{4}\right) \right].$$

If  $\nu[0] \in \mathbb{Z}$ , it computes one extra derivative and removes the singularity (it is then assumed that  $\nu[1] \neq 0$ ). As currently implemented, the output is indeterminate if  $\nu[0]$  is nonexact and contains an integer.

void **acb\_hypgeom\_bessel\_k\_of1**(*acb\_t res*, const *acb\_t nu*, const *acb\_t z*, *slong prec*)

Computes the modified Bessel function of the second kind from

$$K_\nu(z) = \frac{1}{2} \left[ \left(\frac{z}{2}\right)^{-\nu} \Gamma(\nu) {}_0F_1\left(1-\nu, \frac{z^2}{4}\right) - \left(\frac{z}{2}\right)^\nu \frac{\pi}{\nu \sin(\pi\nu) \Gamma(\nu)} {}_0F_1\left(\nu+1, \frac{z^2}{4}\right) \right]$$

if  $\nu \notin \mathbb{Z}$ . If  $\nu \in \mathbb{Z}$ , it computes the limit value via **acb\_hypgeom\_bessel\_k\_of1\_series()**. As currently implemented, the output is indeterminate if  $\nu$  is nonexact and contains an integer.

void **acb\_hypgeom\_bessel\_k**(*acb\_t res*, const *acb\_t nu*, const *acb\_t z*, *slong prec*)

Computes the modified Bessel function of the second kind  $K_\nu(z)$  using an automatic algorithm choice.

## 7.1.7 Airy functions

The Airy functions are linearly independent solutions of the differential equation  $y'' - zy = 0$ . All solutions are entire functions. The standard solutions are denoted  $Ai(z)$ ,  $Bi(z)$ . For negative  $z$ , both functions are oscillatory. For positive  $z$ , the first function decreases exponentially while the second increases exponentially.

The Airy functions can be expressed in terms of Bessel functions of fractional order, but this is inconvenient since such formulas only hold piecewise (due to the Stokes phenomenon). Computation of the Airy functions can also be optimized more than Bessel functions in general. We therefore provide a dedicated interface for evaluating Airy functions.

The following methods optionally compute  $(Ai(z), Ai'(z), Bi(z), Bi'(z))$  simultaneously. Any of the four function values can be omitted by passing *NULL* for the unwanted output variables, speeding up the evaluation.

```
void acb_hypgeom_airy_direct(acb_t ai, acb_t ai_prime, acb_t bi, acb_t bi_prime, const
                             acb_t z, slong n, slong prec)
```

Computes the Airy functions using direct series expansions truncated at  $n$  terms. Error bounds are included in the output.

```
void acb_hypgeom_airy_asymp(acb_t ai, acb_t ai_prime, acb_t bi, acb_t bi_prime, const
                             acb_t z, slong n, slong prec)
```

Computes the Airy functions using asymptotic expansions truncated at  $n$  terms. Error bounds are included in the output. For details about how the error bounds are computed, see *Asymptotic series for Airy functions*.

```
void acb_hypgeom_airy_bound(mag_t ai, mag_t ai_prime, mag_t bi, mag_t bi_prime, const
                             acb_t z)
```

Computes bounds for the Airy functions using first-order asymptotic expansions together with error bounds. This function uses some shortcuts to make it slightly faster than calling *acb\_hypgeom\_airy\_asymp()* with  $n = 1$ .

```
void acb_hypgeom_airy(acb_t ai, acb_t ai_prime, acb_t bi, acb_t bi_prime, const acb_t z,
                      slong prec)
```

Computes Airy functions using an automatic algorithm choice.

We use *acb\_hypgeom\_airy\_asymp()* whenever this gives full accuracy and *acb\_hypgeom\_airy\_direct()* otherwise. In the latter case, we first use hardware double precision arithmetic to determine an accurate estimate of the working precision needed to compute the Airy functions accurately for given  $z$ . This estimate is obtained by comparing the leading-order asymptotic estimate of the Airy functions with the magnitude of the largest term in the power series. The estimate is generic in the sense that it does not take into account vanishing near the roots of the functions. We subsequently evaluate the power series at the midpoint of  $z$  and bound the propagated error using derivatives. Derivatives are bounded using *acb\_hypgeom\_airy\_bound()*.

```
void acb_hypgeom_airy_jet(acb_ptr ai, acb_ptr bi, const acb_t z, slong len, slong prec)
```

Writes to *ai* and *bi* the respective Taylor expansions of the Airy functions at the point  $z$ , truncated to length *len*. Either of the outputs can be *NULL* to avoid computing that function. The variable  $z$  is not allowed to be aliased with the outputs. To simplify the implementation, this method does not compute the series expansions of the primed versions directly; these are easily obtained by computing one extra coefficient and differentiating the output with *\_acb\_poly\_derivative()*.

```
void _acb_hypgeom_airy_series(acb_ptr ai, acb_ptr ai_prime, acb_ptr bi, acb_ptr bi_prime,
                             acb_srcptr z, slong zlen, slong len, slong prec)
```

```
void acb_hypgeom_airy_series(acb_poly_t ai, acb_poly_t ai_prime, acb_poly_t bi,
                             acb_poly_t bi_prime, const acb_poly_t z, slong len, slong prec)
```

Computes the Airy functions evaluated at the power series  $z$ , truncated to length *len*. As with the other Airy methods, any of the outputs can be *NULL*.

## 7.1.8 Incomplete gamma and beta functions

void `acb_hypgeom_gamma_upper_asymp`(*acb\_t* res, const *acb\_t* s, const *acb\_t* z, int *regularized*,  
*slong prec*)

void `acb_hypgeom_gamma_upper_if1a`(*acb\_t* res, const *acb\_t* s, const *acb\_t* z, int *regularized*,  
*slong prec*)

void `acb_hypgeom_gamma_upper_if1b`(*acb\_t* res, const *acb\_t* s, const *acb\_t* z, int *regularized*,  
*slong prec*)

void `acb_hypgeom_gamma_upper_singular`(*acb\_t* res, *slong* s, const *acb\_t* z, int *regularized*,  
*slong prec*)

void `acb_hypgeom_gamma_upper`(*acb\_t* res, const *acb\_t* s, const *acb\_t* z, int *regularized*,  
*slong prec*)

If *regularized* is 0, computes the upper incomplete gamma function  $\Gamma(s, z)$ .

If *regularized* is 1, computes the regularized upper incomplete gamma function  $Q(s, z) = \Gamma(s, z)/\Gamma(s)$ .

If *regularized* is 2, computes the generalized exponential integral  $z^{-s}\Gamma(s, z) = E_{1-s}(z)$  instead (this option is mainly intended for internal use; `acb_hypgeom_expint()` is the intended interface for computing the exponential integral).

The different methods respectively implement the formulas

$$\Gamma(s, z) = e^{-z}U(1-s, 1-s, z)$$

$$\Gamma(s, z) = \Gamma(s) - \frac{z^s}{s} {}_1F_1(s, s+1, -z)$$

$$\Gamma(s, z) = \Gamma(s) - \frac{z^s e^{-z}}{s} {}_1F_1(1, s+1, z)$$

$$\Gamma(s, z) = \frac{(-1)^n}{n!} (\psi(n+1) - \log(z)) + \frac{(-1)^n}{(n+1)!} z {}_2F_2(1, 1, 2, 2+n, -z) - z^{-n} \sum_{k=0}^{n-1} \frac{(-z)^k}{(k-n)k!}, \quad n = -s \in \mathbb{Z}_{\geq 0}$$

and an automatic algorithm choice. The automatic version also handles other special input such as  $z = 0$  and  $s = 1, 2, 3$ . The *singular* version evaluates the finite sum directly and therefore assumes that  $s$  is not too large.

void `_acb_hypgeom_gamma_upper_series`(*acb\_ptr* res, const *acb\_t* s, *acb\_srcptr* z, *slong* zlen,  
int *regularized*, *slong* n, *slong prec*)

void `acb_hypgeom_gamma_upper_series`(*acb\_poly\_t* res, const *acb\_t* s, const *acb\_poly\_t* z,  
int *regularized*, *slong* n, *slong prec*)

Sets *res* to an upper incomplete gamma function where  $s$  is a constant and  $z$  is a power series, truncated to length  $n$ . The *regularized* argument has the same interpretation as in `acb_hypgeom_gamma_upper()`.

void `acb_hypgeom_gamma_lower`(*acb\_t* res, const *acb\_t* s, const *acb\_t* z, int *regularized*,  
*slong prec*)

If *regularized* is 0, computes the lower incomplete gamma function  $\gamma(s, z) = \frac{z^s}{s} {}_1F_1(s, s+1, -z)$ .

If *regularized* is 1, computes the regularized lower incomplete gamma function  $P(s, z) = \gamma(s, z)/\Gamma(s)$ .

If *regularized* is 2, computes a further regularized lower incomplete gamma function  $\gamma^*(s, z) = z^{-s}P(s, z)$ .

void `_acb_hypgeom_gamma_lower_series`(*acb\_ptr* res, const *acb\_t* s, *acb\_srcptr* z, *slong* zlen,  
int *regularized*, *slong* n, *slong prec*)

void `acb_hypgeom_gamma_lower_series`(*acb\_poly\_t* res, const *acb\_t* s, const *acb\_poly\_t* z,  
int *regularized*, *slong* n, *slong prec*)

Sets *res* to an lower incomplete gamma function where  $s$  is a constant and  $z$  is a power series, truncated to length  $n$ . The *regularized* argument has the same interpretation as in `acb_hypgeom_gamma_lower()`.

void **acb\_hypgeom\_beta\_lower**(*acb\_t* res, const *acb\_t* a, const *acb\_t* b, const *acb\_t* z, int *regularized*, *slong prec*)

Computes the (lower) incomplete beta function, defined by  $B(a, b; z) = \int_0^z t^{a-1}(1-t)^{b-1}$ , optionally the regularized incomplete beta function  $I(a, b; z) = B(a, b; z)/B(a, b; 1)$ .

In general, the integral must be interpreted using analytic continuation. The precise definitions for all parameter values are

$$B(a, b; z) = \frac{z^a}{a} {}_2F_1(a, 1-b, a+1, z)$$

$$I(a, b; z) = \frac{\Gamma(a+b)}{\Gamma(b)} z^a {}_2\tilde{F}_1(a, 1-b, a+1, z).$$

Note that both functions with this definition are undefined for nonpositive integer  $a$ , and  $I$  is undefined for nonpositive integer  $a+b$ .

void **\_acb\_hypgeom\_beta\_lower\_series**(*acb\_ptr* res, const *acb\_t* a, const *acb\_t* b, *acb\_srcptr* z, *slong* zlen, int *regularized*, *slong* n, *slong prec*)

void **acb\_hypgeom\_beta\_lower\_series**(*acb\_poly\_t* res, const *acb\_t* a, const *acb\_t* b, const *acb\_poly\_t* z, int *regularized*, *slong* n, *slong prec*)

Sets *res* to the lower incomplete beta function  $B(a, b; z)$  (optionally the regularized version  $I(a, b; z)$ ) where  $a$  and  $b$  are constants and  $z$  is a power series, truncating the result to length  $n$ . The underscore method requires positive lengths and does not support aliasing.

## 7.1.9 Exponential and trigonometric integrals

The branch cut conventions of the following functions match Mathematica.

void **acb\_hypgeom\_expint**(*acb\_t* res, const *acb\_t* s, const *acb\_t* z, *slong prec*)

Computes the generalized exponential integral  $E_s(z)$ . This is a trivial wrapper of *acb\_hypgeom\_gamma\_upper()*.

void **acb\_hypgeom\_ei\_asymp**(*acb\_t* res, const *acb\_t* z, *slong prec*)

void **acb\_hypgeom\_ei\_2f2**(*acb\_t* res, const *acb\_t* z, *slong prec*)

void **acb\_hypgeom\_ei**(*acb\_t* res, const *acb\_t* z, *slong prec*)

Computes the exponential integral  $Ei(z)$ , respectively using

$$Ei(z) = -e^z U(1, 1, -z) - \log(-z) + \frac{1}{2} \left( \log(z) - \log\left(\frac{1}{z}\right) \right)$$

$$Ei(z) = z {}_2F_2(1, 1; 2, 2; z) + \gamma + \frac{1}{2} \left( \log(z) - \log\left(\frac{1}{z}\right) \right)$$

and an automatic algorithm choice.

void **\_acb\_hypgeom\_ei\_series**(*acb\_ptr* res, *acb\_srcptr* z, *slong* zlen, *slong* len, *slong prec*)

void **acb\_hypgeom\_ei\_series**(*acb\_poly\_t* res, const *acb\_poly\_t* z, *slong* len, *slong prec*)

Computes the exponential integral of the power series  $z$ , truncated to length  $len$ .

void **acb\_hypgeom\_si\_asymp**(*acb\_t* res, const *acb\_t* z, *slong prec*)

void **acb\_hypgeom\_si\_1f2**(*acb\_t* res, const *acb\_t* z, *slong prec*)

void **acb\_hypgeom\_si**(*acb\_t* res, const *acb\_t* z, *slong prec*)

Computes the sine integral  $Si(z)$ , respectively using

$$Si(z) = \frac{i}{2} [e^{iz} U(1, 1, -iz) - e^{-iz} U(1, 1, iz) + \log(-iz) - \log(iz)]$$

$$Si(z) = z {}_1F_2\left(\frac{1}{2}; \frac{3}{2}, \frac{3}{2}; -\frac{z^2}{4}\right)$$

and an automatic algorithm choice.

void `_acb_hypgeom_si_series`(*acb\_ptr* res, *acb\_srcptr* z, *slong* zlen, *slong* len, *slong* prec)

void `acb_hypgeom_si_series`(*acb\_poly\_t* res, const *acb\_poly\_t* z, *slong* len, *slong* prec)  
Computes the sine integral of the power series z, truncated to length len.

void `acb_hypgeom_ci_asymp`(*acb\_t* res, const *acb\_t* z, *slong* prec)

void `acb_hypgeom_ci_2f3`(*acb\_t* res, const *acb\_t* z, *slong* prec)

void `acb_hypgeom_ci`(*acb\_t* res, const *acb\_t* z, *slong* prec)  
Computes the cosine integral Ci(z), respectively using

$$\text{Ci}(z) = \log(z) - \frac{1}{2} [e^{iz}U(1, 1, -iz) + e^{-iz}U(1, 1, iz) + \log(-iz) + \log(iz)]$$

$$\text{Ci}(z) = -\frac{z^2}{4} {}_2F_3(1, 1; 2, 2, \frac{3}{2}; -\frac{z^2}{4}) + \log(z) + \gamma$$

and an automatic algorithm choice.

void `_acb_hypgeom_ci_series`(*acb\_ptr* res, *acb\_srcptr* z, *slong* zlen, *slong* len, *slong* prec)

void `acb_hypgeom_ci_series`(*acb\_poly\_t* res, const *acb\_poly\_t* z, *slong* len, *slong* prec)  
Computes the cosine integral of the power series z, truncated to length len.

void `acb_hypgeom_shi`(*acb\_t* res, const *acb\_t* z, *slong* prec)

Computes the hyperbolic sine integral Shi(z) = -iSi(iz). This is a trivial wrapper of `acb_hypgeom_si()`.

void `_acb_hypgeom_shi_series`(*acb\_ptr* res, *acb\_srcptr* z, *slong* zlen, *slong* len, *slong* prec)

void `acb_hypgeom_shi_series`(*acb\_poly\_t* res, const *acb\_poly\_t* z, *slong* len, *slong* prec)  
Computes the hyperbolic sine integral of the power series z, truncated to length len.

void `acb_hypgeom_chi_asymp`(*acb\_t* res, const *acb\_t* z, *slong* prec)

void `acb_hypgeom_chi_2f3`(*acb\_t* res, const *acb\_t* z, *slong* prec)

void `acb_hypgeom_chi`(*acb\_t* res, const *acb\_t* z, *slong* prec)  
Computes the hyperbolic cosine integral Chi(z), respectively using

$$\text{Chi}(z) = -\frac{1}{2} [e^zU(1, 1, -z) + e^{-z}U(1, 1, z) + \log(-z) - \log(z)]$$

$$\text{Chi}(z) = \frac{z^2}{4} {}_2F_3(1, 1; 2, 2, \frac{3}{2}; \frac{z^2}{4}) + \log(z) + \gamma$$

and an automatic algorithm choice.

void `_acb_hypgeom_chi_series`(*acb\_ptr* res, *acb\_srcptr* z, *slong* zlen, *slong* len, *slong* prec)

void `acb_hypgeom_chi_series`(*acb\_poly\_t* res, const *acb\_poly\_t* z, *slong* len, *slong* prec)  
Computes the hyperbolic cosine integral of the power series z, truncated to length len.

void `acb_hypgeom_li`(*acb\_t* res, const *acb\_t* z, int offset, *slong* prec)

If *offset* is zero, computes the logarithmic integral li(z) = Ei(log(z)).

If *offset* is nonzero, computes the offset logarithmic integral Li(z) = li(z) - li(2).

void `_acb_hypgeom_li_series`(*acb\_ptr* res, *acb\_srcptr* z, *slong* zlen, int offset, *slong* len, *slong* prec)

void `acb_hypgeom_li_series`(*acb\_poly\_t* res, const *acb\_poly\_t* z, int offset, *slong* len, *slong* prec)

Computes the logarithmic integral (optionally the offset version) of the power series z, truncated to length len.

### 7.1.10 Gauss hypergeometric function

The following methods compute the Gauss hypergeometric function

$$F(z) = {}_2F_1(a, b, c, z) = \sum_{k=0}^{\infty} \frac{(a)_k (b)_k}{(c)_k} \frac{z^k}{k!}$$

or the regularized version  $\mathbf{F}(z) = \mathbf{F}(a, b, c, z) = {}_2F_1(a, b, c, z)/\Gamma(c)$  if the flag *regularized* is set.

void **acb\_hypgeom\_2f1\_continuation**(*acb\_t* res0, *acb\_t* res1, const *acb\_t* a, const *acb\_t* b, const *acb\_t* c, const *acb\_t* z0, const *acb\_t* z1, const *acb\_t* f0, const *acb\_t* f1, *slong* prec)

Given  $F(z_0), F'(z_0)$  in  $f0, f1$ , sets *res0* and *res1* to  $F(z_1), F'(z_1)$  by integrating the hypergeometric differential equation along a straight-line path. The evaluation points should be well-isolated from the singular points 0 and 1.

void **acb\_hypgeom\_2f1\_series\_direct**(*acb\_poly\_t* res, const *acb\_poly\_t* a, const *acb\_poly\_t* b, const *acb\_poly\_t* c, const *acb\_poly\_t* z, int *regularized*, *slong* len, *slong* prec)

Computes  $F(z)$  of the given power series truncated to length *len*, using direct summation of the hypergeometric series.

void **acb\_hypgeom\_2f1\_direct**(*acb\_t* res, const *acb\_t* a, const *acb\_t* b, const *acb\_t* c, const *acb\_t* z, int *regularized*, *slong* prec)

Computes  $F(z)$  using direct summation of the hypergeometric series.

void **acb\_hypgeom\_2f1\_transform**(*acb\_t* res, const *acb\_t* a, const *acb\_t* b, const *acb\_t* c, const *acb\_t* z, int *flags*, int *which*, *slong* prec)

void **acb\_hypgeom\_2f1\_transform\_limit**(*acb\_t* res, const *acb\_t* a, const *acb\_t* b, const *acb\_t* c, const *acb\_t* z, int *regularized*, int *which*, *slong* prec)

Computes  $F(z)$  using an argument transformation determined by the flag *which*. Legal values are 1 for  $z/(z-1)$ , 2 for  $1/z$ , 3 for  $1/(1-z)$ , 4 for  $1-z$ , and 5 for  $1-1/z$ .

The *transform\_limit* version assumes that *which* is not 1. If *which* is 2 or 3, it assumes that  $b-a$  represents an exact integer. If *which* is 4 or 5, it assumes that  $c-a-b$  represents an exact integer. In these cases, it computes the correct limit value.

See [acb\\_hypgeom\\_2f1\(\)](#) for the meaning of *flags*.

void **acb\_hypgeom\_2f1\_corner**(*acb\_t* res, const *acb\_t* a, const *acb\_t* b, const *acb\_t* c, const *acb\_t* z, int *regularized*, *slong* prec)

Computes  $F(z)$  near the corner cases  $\exp(\pm\pi i\sqrt{3})$  by analytic continuation.

int **acb\_hypgeom\_2f1\_choose**(const *acb\_t* z)

Chooses a method to compute the function based on the location of  $z$  in the complex plane. If the return value is 0, direct summation should be used. If the return value is 1 to 5, the transformation with this index in [acb\\_hypgeom\\_2f1\\_transform\(\)](#) should be used. If the return value is 6, the corner case algorithm should be used.

void **acb\_hypgeom\_2f1**(*acb\_t* res, const *acb\_t* a, const *acb\_t* b, const *acb\_t* c, const *acb\_t* z, int *flags*, *slong* prec)

Computes  $F(z)$  or  $\mathbf{F}(z)$  using an automatic algorithm choice.

The following bit fields can be set in *flags*:

- **ACB\_HYPGEOM\_2F1\_REGULARIZED** - computes the regularized hypergeometric function  $\mathbf{F}(z)$ . Setting *flags* to 1 is the same as just toggling this option.
- **ACB\_HYPGEOM\_2F1\_AB** -  $a-b$  is an integer.
- **ACB\_HYPGEOM\_2F1\_ABC** -  $a+b-c$  is an integer.
- **ACB\_HYPGEOM\_2F1\_AC** -  $a-c$  is an integer.
- **ACB\_HYPGEOM\_2F1\_BC** -  $b-c$  is an integer.

The last four flags can be set to indicate that the respective parameter differences are known to represent exact integers, even if the input intervals are inexact. This allows the correct limits to be evaluated when applying transformation formulas. For example, to evaluate  ${}_2F_1(\sqrt{2}, 1/2, \sqrt{2} + 3/2, 9/10)$ , the *ABC* flag should be set. If not set, the result will be an indeterminate interval due to internally dividing by an interval containing zero. If the parameters are exact floating-point numbers (including exact integers or half-integers), then the limits are computed automatically, and setting these flags is unnecessary.

Currently, only the *AB* and *ABC* flags are used this way; the *AC* and *BC* flags might be used in the future.

### 7.1.11 Orthogonal polynomials and functions

void **acb\_hypgeom\_chebyshev\_t**(*acb\_t res*, const *acb\_t n*, const *acb\_t z*, *slong prec*)

void **acb\_hypgeom\_chebyshev\_u**(*acb\_t res*, const *acb\_t n*, const *acb\_t z*, *slong prec*)

Computes the Chebyshev polynomial (or Chebyshev function) of first or second kind

$$T_n(z) = {}_2F_1\left(-n, n, \frac{1}{2}, \frac{1-z}{2}\right)$$

$$U_n(z) = (n+1) {}_2F_1\left(-n, n+2, \frac{3}{2}, \frac{1-z}{2}\right).$$

The hypergeometric series definitions are only used for computation near the point 1. In general, trigonometric representations are used. For word-size integer *n*, **acb\_chebyshev\_t\_ui()** and **acb\_chebyshev\_u\_ui()** are called.

void **acb\_hypgeom\_jacobi\_p**(*acb\_t res*, const *acb\_t n*, const *acb\_t a*, const *acb\_t b*, const *acb\_t z*, *slong prec*)

Computes the Jacobi polynomial (or Jacobi function)

$$P_n^{(a,b)}(z) = \frac{(a+1)_n}{\Gamma(n+1)} {}_2F_1\left(-n, n+a+b+1, a+1, \frac{1-z}{2}\right).$$

For nonnegative integer *n*, this is a polynomial in *a*, *b* and *z*, even when the parameters are such that the hypergeometric series is undefined. In such cases, the polynomial is evaluated using direct methods.

void **acb\_hypgeom\_gegenbauer\_c**(*acb\_t res*, const *acb\_t n*, const *acb\_t m*, const *acb\_t z*, *slong prec*)

Computes the Gegenbauer polynomial (or Gegenbauer function)

$$C_n^m(z) = \frac{(2m)_n}{\Gamma(n+1)} {}_2F_1\left(-n, 2m+n, m+\frac{1}{2}, \frac{1-z}{2}\right).$$

For nonnegative integer *n*, this is a polynomial in *m* and *z*, even when the parameters are such that the hypergeometric series is undefined. In such cases, the polynomial is evaluated using direct methods.

void **acb\_hypgeom\_laguerre\_l**(*acb\_t res*, const *acb\_t n*, const *acb\_t m*, const *acb\_t z*, *slong prec*)

Computes the Laguerre polynomial (or Laguerre function)

$$L_n^m(z) = \frac{(m+1)_n}{\Gamma(n+1)} {}_1F_1(-n, m+1, z).$$

For nonnegative integer *n*, this is a polynomial in *m* and *z*, even when the parameters are such that the hypergeometric series is undefined. In such cases, the polynomial is evaluated using direct methods.

There are at least two incompatible ways to define the Laguerre function when *n* is a negative integer. One possibility when *m* = 0 is to define  $L_{-n}^0(z) = e^z L_{n-1}^0(-z)$ . Another possibility is to cover this case with the recurrence relation  $L_{n-1}^m(z) + L_n^{m-1}(z) = L_n^m(z)$ . Currently, we leave this case undefined (returning indeterminate).

void **acb\_hypgeom\_hermite\_h**(*acb\_t* res, const *acb\_t* n, const *acb\_t* z, *slong* prec)  
 Computes the Hermite polynomial (or Hermite function)

$$H_n(z) = 2^n \sqrt{\pi} \left( \frac{1}{\Gamma((1-n)/2)} {}_1F_1 \left( -\frac{n}{2}, \frac{1}{2}, z^2 \right) - \frac{2z}{\Gamma(-n/2)} {}_1F_1 \left( \frac{1-n}{2}, \frac{3}{2}, z^2 \right) \right).$$

void **acb\_hypgeom\_legendre\_p**(*acb\_t* res, const *acb\_t* n, const *acb\_t* m, const *acb\_t* z, int *type*, *slong* prec)  
 Sets *res* to the associated Legendre function of the first kind evaluated for degree *n*, order *m*, and argument *z*. When *m* is zero, this reduces to the Legendre polynomial  $P_n(z)$ .

Many different branch cut conventions appear in the literature. If *type* is 0, the version

$$P_n^m(z) = \frac{(1+z)^{m/2}}{(1-z)^{m/2}} \mathbf{F} \left( -n, n+1, 1-m, \frac{1-z}{2} \right)$$

is computed, and if *type* is 1, the alternative version

$$\mathcal{P}_n^m(z) = \frac{(z+1)^{m/2}}{(z-1)^{m/2}} \mathbf{F} \left( -n, n+1, 1-m, \frac{1-z}{2} \right).$$

is computed. Type 0 and type 1 respectively correspond to type 2 and type 3 in *Mathematica* and *mpmath*.

void **acb\_hypgeom\_legendre\_q**(*acb\_t* res, const *acb\_t* n, const *acb\_t* m, const *acb\_t* z, int *type*, *slong* prec)  
 Sets *res* to the associated Legendre function of the second kind evaluated for degree *n*, order *m*, and argument *z*. When *m* is zero, this reduces to the Legendre function  $Q_n(z)$ .

Many different branch cut conventions appear in the literature. If *type* is 0, the version

$$Q_n^m(z) = \frac{\pi}{2 \sin(\pi m)} \left( \cos(\pi m) P_n^m(z) - \frac{\Gamma(1+m+n)}{\Gamma(1-m+n)} P_n^{-m}(z) \right)$$

is computed, and if *type* is 1, the alternative version

$$\mathcal{Q}_n^m(z) = \frac{\pi}{2 \sin(\pi m)} e^{\pi i m} \left( \mathcal{P}_n^m(z) - \frac{\Gamma(1+m+n)}{\Gamma(1-m+n)} \mathcal{P}_n^{-m}(z) \right)$$

is computed. Type 0 and type 1 respectively correspond to type 2 and type 3 in *Mathematica* and *mpmath*.

When *m* is an integer, either expression is interpreted as a limit. We make use of the connection formulas [WQ3a], [WQ3b] and [WQ3c] to allow computing the function even in the limiting case. (The formula [WQ3d] would be useful, but is incorrect in the lower half plane.)

void **acb\_hypgeom\_legendre\_p\_uuii\_rec**(*acb\_t* res, *ulong* n, *ulong* m, const *acb\_t* z, *slong* prec)  
 For nonnegative integer *n* and *m*, uses recurrence relations to evaluate  $(1-z^2)^{-m/2} P_n^m(z)$  which is a polynomial in *z*.

void **acb\_hypgeom\_spherical\_y**(*acb\_t* res, *slong* n, *slong* m, const *acb\_t* theta, const *acb\_t* phi, *slong* prec)  
 Computes the spherical harmonic of degree *n*, order *m*, latitude angle *theta*, and longitude angle *phi*, normalized such that

$$Y_n^m(\theta, \phi) = \sqrt{\frac{2n+1}{4\pi} \frac{(n-m)!}{(n+m)!}} e^{im\phi} P_n^m(\cos(\theta)).$$

The definition is extended to negative *m* and *n* by symmetry. This function is a polynomial in  $\cos(\theta)$  and  $\sin(\theta)$ . We evaluate it using **acb\_hypgeom\_legendre\_p\_uuii\_rec()**.

## 7.1.12 Dilogarithm

The dilogarithm function is given by  $\text{Li}_2(z) = -\int_0^z \frac{\log(1-t)}{t} dt = z {}_3F_2(1, 1, 1, 2, 2, z)$ .

void **acb\_hypgeom\_dilog\_bernoulli**(*acb\_t res*, const *acb\_t z*, *slong prec*)

Computes the dilogarithm using a series expansion in  $w = \log(z)$ , with rate of convergence  $|w/(2\pi)|^n$ . This provides good convergence near  $z = e^{\pm i\pi/3}$ , where hypergeometric series expansions fail. Since the coefficients involve Bernoulli numbers, this method should only be used at moderate precision.

void **acb\_hypgeom\_dilog\_zero\_taylor**(*acb\_t res*, const *acb\_t z*, *slong prec*)

Computes the dilogarithm for  $z$  close to 0 using the hypergeometric series (effective only when  $|z| \ll 1$ ).

void **acb\_hypgeom\_dilog\_zero**(*acb\_t res*, const *acb\_t z*, *slong prec*)

Computes the dilogarithm for  $z$  close to 0, using the bit-burst algorithm instead of the hypergeometric series directly at very high precision.

void **acb\_hypgeom\_dilog\_transform**(*acb\_t res*, const *acb\_t z*, int *algorithm*, *slong prec*)

Computes the dilogarithm by applying one of the transformations  $1/z$ ,  $1-z$ ,  $z/(z-1)$ ,  $1/(1-z)$ , indexed by *algorithm* from 1 to 4, and calling **acb\_hypgeom\_dilog\_zero()** with the reduced variable. Alternatively, for *algorithm* between 5 and 7, starts from the respective point  $\pm i$ ,  $(1 \pm i)/2$ ,  $(1 \pm i)/2$  (with the sign chosen according to the midpoint of  $z$ ) and computes the dilogarithm by the bit-burst method.

void **acb\_hypgeom\_dilog\_continuation**(*acb\_t res*, const *acb\_t a*, const *acb\_t z*, *slong prec*)

Computes  $\text{Li}_2(z) - \text{Li}_2(a)$  using Taylor expansion at  $a$ . Binary splitting is used. Both  $a$  and  $z$  should be well isolated from the points 0 and 1, except that  $a$  may be exactly 0. If the straight line path from  $a$  to  $b$  crosses the branch cut, this method provides continuous analytic continuation instead of computing the principal branch.

void **acb\_hypgeom\_dilog\_bitburst**(*acb\_t res*, *acb\_t z0*, const *acb\_t z*, *slong prec*)

Sets  $z0$  to a point with short bit expansion close to  $z$  and sets *res* to  $\text{Li}_2(z) - \text{Li}_2(z0)$ , computed using the bit-burst algorithm.

void **acb\_hypgeom\_dilog**(*acb\_t res*, const *acb\_t z*, *slong prec*)

Computes the dilogarithm using a default algorithm choice.

## 7.2 arb\_hypgeom.h – hypergeometric functions of real variables

See *acb\_hypgeom.h – hypergeometric functions of complex variables* for the implementation of hypergeometric functions.

For convenience, this module provides corresponding functions for direct use with the real types *arb\_t* and *arb\_poly\_t*. Most methods are simple wrappers around the complex versions, with a tiny amount of extra overhead for conversions, but in some cases the functions in this module will be faster. In the future, code that is further optimized specifically for real variables might be added to this module.

### 7.2.1 Generalized hypergeometric function

void **arb\_hypgeom\_pfq**(*arb\_t res*, *arb\_srcptr a*, *slong p*, *arb\_srcptr b*, *slong q*, const *arb\_t z*, int *regularized*, *slong prec*)

Computes the generalized hypergeometric function  ${}_pF_q(z)$ , or the regularized version if *regularized* is set.

### 7.2.2 Confluent hypergeometric functions

void **arb\_hypgeom\_0f1**(*arb\_t res*, const *arb\_t a*, const *arb\_t z*, int *regularized*, *slong prec*)

Computes the confluent hypergeometric limit function  ${}_0F_1(a, z)$ , or  $\frac{1}{\Gamma(a)} {}_0F_1(a, z)$  if *regularized* is

set.

void **arb\_hypgeom\_m**(*arb\_t* res, const *arb\_t* a, const *arb\_t* b, const *arb\_t* z, int *regularized*,  
                             *slong prec*)  
 Computes the confluent hypergeometric function  $M(a, b, z) = {}_1F_1(a, b, z)$ , or  $\mathbf{M}(a, b, z) = \frac{1}{\Gamma(b)} {}_1F_1(a, b, z)$  if *regularized* is set.

void **arb\_hypgeom\_1f1**(*arb\_t* res, const *arb\_t* a, const *arb\_t* b, const *arb\_t* z, int *regularized*,  
                             *slong prec*)  
 Alias for **arb\_hypgeom\_m**( ).

void **arb\_hypgeom\_u**(*arb\_t* res, const *arb\_t* a, const *arb\_t* b, const *arb\_t* z, *slong prec*)  
 Computes the confluent hypergeometric function  $U(a, b, z)$ .

### 7.2.3 Gauss hypergeometric function

void **arb\_hypgeom\_2f1**(*arb\_t* res, const *arb\_t* a, const *arb\_t* b, const *arb\_t* c, const *arb\_t* z,  
                             int *regularized*, *slong prec*)  
 Computes the Gauss hypergeometric function  ${}_2F_1(a, b, c, z)$ , or  $\mathbf{F}(a, b, c, z) = \frac{1}{\Gamma(c)} {}_2F_1(a, b, c, z)$  if *regularized* is set.

Additional evaluation flags can be passed via the *regularized* argument; see **acb\_hypgeom\_2f1**( ) for documentation.

### 7.2.4 Error functions and Fresnel integrals

void **arb\_hypgeom\_erf**(*arb\_t* res, const *arb\_t* z, *slong prec*)  
 Computes the error function  $\operatorname{erf}(z)$ .

void **\_arb\_hypgeom\_erf\_series**(*arb\_ptr* res, *arb\_srcptr* z, *slong* zlen, *slong* len, *slong* prec)

void **arb\_hypgeom\_erf\_series**(*arb\_poly\_t* res, const *arb\_poly\_t* z, *slong* len, *slong* prec)  
 Computes the error function of the power series *z*, truncated to length *len*.

void **arb\_hypgeom\_erfc**(*arb\_t* res, const *arb\_t* z, *slong prec*)  
 Computes the complementary error function  $\operatorname{erfc}(z) = 1 - \operatorname{erf}(z)$ . This function avoids catastrophic cancellation for large positive *z*.

void **\_arb\_hypgeom\_erfc\_series**(*arb\_ptr* res, *arb\_srcptr* z, *slong* zlen, *slong* len, *slong* prec)

void **arb\_hypgeom\_erfc\_series**(*arb\_poly\_t* res, const *arb\_poly\_t* z, *slong* len, *slong* prec)  
 Computes the complementary error function of the power series *z*, truncated to length *len*.

void **arb\_hypgeom\_erfi**(*arb\_t* res, const *arb\_t* z, *slong prec*)  
 Computes the imaginary error function  $\operatorname{erfi}(z) = -i \operatorname{erf}(iz)$ .

void **\_arb\_hypgeom\_erfi\_series**(*arb\_ptr* res, *arb\_srcptr* z, *slong* zlen, *slong* len, *slong* prec)

void **arb\_hypgeom\_erfi\_series**(*arb\_poly\_t* res, const *arb\_poly\_t* z, *slong* len, *slong* prec)  
 Computes the imaginary error function of the power series *z*, truncated to length *len*.

void **arb\_hypgeom\_fresnel**(*arb\_t* res1, *arb\_t* res2, const *arb\_t* z, int *normalized*, *slong prec*)  
 Sets *res1* to the Fresnel sine integral  $S(z)$  and *res2* to the Fresnel cosine integral  $C(z)$ . Optionally, just a single function can be computed by passing *NULL* as the other output variable. The definition  $S(z) = \int_0^z \sin(t^2) dt$  is used if *normalized* is 0, and  $S(z) = \int_0^z \sin(\frac{1}{2}\pi t^2) dt$  is used if *normalized* is 1 (the latter is the Abramowitz & Stegun convention).  $C(z)$  is defined analogously.

void **\_arb\_hypgeom\_fresnel\_series**(*arb\_ptr* res1, *arb\_ptr* res2, *arb\_srcptr* z, *slong* zlen,  
                                     int *normalized*, *slong* len, *slong* prec)

void **arb\_hypgeom\_fresnel\_series**(*arb\_poly\_t* res1, *arb\_poly\_t* res2, const *arb\_poly\_t* z,  
                                     int *normalized*, *slong* len, *slong* prec)  
 Sets *res1* to the Fresnel sine integral and *res2* to the Fresnel cosine integral of the power series *z*,

truncated to length *len*. Optionally, just a single function can be computed by passing *NULL* as the other output variable.

## 7.2.5 Incomplete gamma and beta functions

void **arb\_hypgeom\_gamma\_upper**(*arb\_t* res, const *arb\_t* s, const *arb\_t* z, int regularized, *slong* prec)

If *regularized* is 0, computes the upper incomplete gamma function  $\Gamma(s, z)$ .

If *regularized* is 1, computes the regularized upper incomplete gamma function  $Q(s, z) = \Gamma(s, z)/\Gamma(s)$ .

If *regularized* is 2, computes the generalized exponential integral  $z^{-s}\Gamma(s, z) = E_{1-s}(z)$  instead (this option is mainly intended for internal use; *arb\_hypgeom\_expint()* is the intended interface for computing the exponential integral).

void **\_arb\_hypgeom\_gamma\_upper\_series**(*arb\_ptr* res, const *arb\_t* s, *arb\_srcptr* z, *slong* zlen, int regularized, *slong* n, *slong* prec)

void **arb\_hypgeom\_gamma\_upper\_series**(*arb\_poly\_t* res, const *arb\_t* s, const *arb\_poly\_t* z, int regularized, *slong* n, *slong* prec)

Sets *res* to an upper incomplete gamma function where *s* is a constant and *z* is a power series, truncated to length *n*. The *regularized* argument has the same interpretation as in *arb\_hypgeom\_gamma\_upper()*.

void **arb\_hypgeom\_gamma\_lower**(*arb\_t* res, const *arb\_t* s, const *arb\_t* z, int regularized, *slong* prec)

If *regularized* is 0, computes the lower incomplete gamma function  $\gamma(s, z) = \frac{z^s}{s} {}_1F_1(s, s+1, -z)$ .

If *regularized* is 1, computes the regularized lower incomplete gamma function  $P(s, z) = \gamma(s, z)/\Gamma(s)$ .

If *regularized* is 2, computes a further regularized lower incomplete gamma function  $\gamma^*(s, z) = z^{-s}P(s, z)$ .

void **\_arb\_hypgeom\_gamma\_lower\_series**(*arb\_ptr* res, const *arb\_t* s, *arb\_srcptr* z, *slong* zlen, int regularized, *slong* n, *slong* prec)

void **arb\_hypgeom\_gamma\_lower\_series**(*arb\_poly\_t* res, const *arb\_t* s, const *arb\_poly\_t* z, int regularized, *slong* n, *slong* prec)

Sets *res* to an lower incomplete gamma function where *s* is a constant and *z* is a power series, truncated to length *n*. The *regularized* argument has the same interpretation as in *arb\_hypgeom\_gamma\_lower()*.

void **arb\_hypgeom\_beta\_lower**(*arb\_t* res, const *arb\_t* a, const *arb\_t* b, const *arb\_t* z, int regularized, *slong* prec)

Computes the (lower) incomplete beta function, defined by  $B(a, b; z) = \int_0^z t^{a-1}(1-t)^{b-1}$ , optionally the regularized incomplete beta function  $I(a, b; z) = B(a, b; z)/B(a, b; 1)$ .

void **\_arb\_hypgeom\_beta\_lower\_series**(*arb\_ptr* res, const *arb\_t* a, const *arb\_t* b, *arb\_srcptr* z, *slong* zlen, int regularized, *slong* n, *slong* prec)

void **arb\_hypgeom\_beta\_lower\_series**(*arb\_poly\_t* res, const *arb\_t* a, const *arb\_t* b, const *arb\_poly\_t* z, int regularized, *slong* n, *slong* prec)

Sets *res* to the lower incomplete beta function  $B(a, b; z)$  (optionally the regularized version  $I(a, b; z)$ ) where *a* and *b* are constants and *z* is a power series, truncating the result to length *n*. The underscore method requires positive lengths and does not support aliasing.

## 7.2.6 Exponential and trigonometric integrals

void **arb\_hypgeom\_expint**(*arb\_t* res, const *arb\_t* s, const *arb\_t* z, *slong* prec)

Computes the generalized exponential integral  $E_s(z)$ .

---

```

void arb_hypgeom_ei(arb_t res, const arb_t z, slong prec)
    Computes the exponential integral  $Ei(z)$ .

void _arb_hypgeom_ei_series(arb_ptr res, arb_srcptr z, slong zlen, slong len, slong prec)

void arb_hypgeom_ei_series(arb_poly_t res, const arb_poly_t z, slong len, slong prec)
    Computes the exponential integral of the power series  $z$ , truncated to length  $len$ .

void arb_hypgeom_si(arb_t res, const arb_t z, slong prec)
    Computes the sine integral  $Si(z)$ .

void _arb_hypgeom_si_series(arb_ptr res, arb_srcptr z, slong zlen, slong len, slong prec)

void arb_hypgeom_si_series(arb_poly_t res, const arb_poly_t z, slong len, slong prec)
    Computes the sine integral of the power series  $z$ , truncated to length  $len$ .

void arb_hypgeom_ci(arb_t res, const arb_t z, slong prec)
    Computes the cosine integral  $Ci(z)$ . The result is indeterminate if  $z < 0$  since the value of the
    function would be complex.

void _arb_hypgeom_ci_series(arb_ptr res, arb_srcptr z, slong zlen, slong len, slong prec)

void arb_hypgeom_ci_series(arb_poly_t res, const arb_poly_t z, slong len, slong prec)
    Computes the cosine integral of the power series  $z$ , truncated to length  $len$ .

void arb_hypgeom_shi(arb_t res, const arb_t z, slong prec)
    Computes the hyperbolic sine integral  $Shi(z) = -i Si(iz)$ .

void _arb_hypgeom_shi_series(arb_ptr res, arb_srcptr z, slong zlen, slong len, slong prec)

void arb_hypgeom_shi_series(arb_poly_t res, const arb_poly_t z, slong len, slong prec)
    Computes the hyperbolic sine integral of the power series  $z$ , truncated to length  $len$ .

void arb_hypgeom_chi(arb_t res, const arb_t z, slong prec)
    Computes the hyperbolic cosine integral  $Chi(z)$ . The result is indeterminate if  $z < 0$  since the
    value of the function would be complex.

void _arb_hypgeom_chi_series(arb_ptr res, arb_srcptr z, slong zlen, slong len, slong prec)

void arb_hypgeom_chi_series(arb_poly_t res, const arb_poly_t z, slong len, slong prec)
    Computes the hyperbolic cosine integral of the power series  $z$ , truncated to length  $len$ .

void arb_hypgeom_li(arb_t res, const arb_t z, int offset, slong prec)
    If offset is zero, computes the logarithmic integral  $li(z) = Ei(\log(z))$ .

    If offset is nonzero, computes the offset logarithmic integral  $Li(z) = li(z) - li(2)$ .

    The result is indeterminate if  $z < 0$  since the value of the function would be complex.

void _arb_hypgeom_li_series(arb_ptr res, arb_srcptr z, slong zlen, int offset, slong len,
    slong prec)

void arb_hypgeom_li_series(arb_poly_t res, const arb_poly_t z, int offset, slong len,
    slong prec)
    Computes the logarithmic integral (optionally the offset version) of the power series  $z$ , truncated
    to length  $len$ .

```

## 7.2.7 Bessel functions

```

void arb_hypgeom_bessel_j(arb_t res, const arb_t nu, const arb_t z, slong prec)
    Computes the Bessel function of the first kind  $J_\nu(z)$ .

void arb_hypgeom_bessel_y(arb_t res, const arb_t nu, const arb_t z, slong prec)
    Computes the Bessel function of the second kind  $Y_\nu(z)$ .

void arb_hypgeom_bessel_jy(arb_t res1, arb_t res2, const arb_t nu, const arb_t z, slong prec)
    Sets res1 to  $J_\nu(z)$  and res2 to  $Y_\nu(z)$ , computed simultaneously.

```

void **arb\_hypgeom\_bessel\_i**(*arb\_t* res, const *arb\_t* nu, const *arb\_t* z, *slong* prec)  
Computes the modified Bessel function of the first kind  $I_\nu(z) = z^\nu (iz)^{-\nu} J_\nu(iz)$ .

void **arb\_hypgeom\_bessel\_k**(*arb\_t* res, const *arb\_t* nu, const *arb\_t* z, *slong* prec)  
Computes the modified Bessel function of the second kind  $K_\nu(z)$ .

## 7.2.8 Airy functions

void **arb\_hypgeom\_airy**(*arb\_t* ai, *arb\_t* ai\_prime, *arb\_t* bi, *arb\_t* bi\_prime, const *arb\_t* z, *slong* prec)  
Computes the Airy functions (Ai(z), Ai'(z), Bi(z), Bi'(z)) simultaneously. Any of the four function values can be omitted by passing *NULL* for the unwanted output variables, speeding up the evaluation.

void **arb\_hypgeom\_airy\_jet**(*arb\_ptr* ai, *arb\_ptr* bi, const *arb\_t* z, *slong* len, *slong* prec)  
Writes to *ai* and *bi* the respective Taylor expansions of the Airy functions at the point *z*, truncated to length *len*. Either of the outputs can be *NULL* to avoid computing that function. The variable *z* is not allowed to be aliased with the outputs. To simplify the implementation, this method does not compute the series expansions of the primed versions directly; these are easily obtained by computing one extra coefficient and differentiating the output with `_arb_poly_derivative()`.

void **\_arb\_hypgeom\_airy\_series**(*arb\_ptr* ai, *arb\_ptr* ai\_prime, *arb\_ptr* bi, *arb\_ptr* bi\_prime, *arb\_srcptr* z, *slong* zlen, *slong* len, *slong* prec)

void **arb\_hypgeom\_airy\_series**(*arb\_poly\_t* ai, *arb\_poly\_t* ai\_prime, *arb\_poly\_t* bi, *arb\_poly\_t* bi\_prime, const *arb\_poly\_t* z, *slong* len, *slong* prec)  
Computes the Airy functions evaluated at the power series *z*, truncated to length *len*. As with the other Airy methods, any of the outputs can be *NULL*.

## 7.2.9 Orthogonal polynomials and functions

void **arb\_hypgeom\_chebyshev\_t**(*arb\_t* res, const *arb\_t* nu, const *arb\_t* z, *slong* prec)

void **arb\_hypgeom\_chebyshev\_u**(*arb\_t* res, const *arb\_t* nu, const *arb\_t* z, *slong* prec)

void **arb\_hypgeom\_jacobi\_p**(*arb\_t* res, const *arb\_t* n, const *arb\_t* a, const *arb\_t* b, const *arb\_t* z, *slong* prec)

void **arb\_hypgeom\_gegenbauer\_c**(*arb\_t* res, const *arb\_t* n, const *arb\_t* m, const *arb\_t* z, *slong* prec)

void **arb\_hypgeom\_laguerre\_l**(*arb\_t* res, const *arb\_t* n, const *arb\_t* m, const *arb\_t* z, *slong* prec)

void **arb\_hypgeom\_hermite\_h**(*arb\_t* res, const *arb\_t* nu, const *arb\_t* z, *slong* prec)  
Computes Chebyshev, Jacobi, Gegenbauer, Laguerre or Hermite polynomials, or their extensions to non-integer orders.

void **arb\_hypgeom\_legendre\_p**(*arb\_t* res, const *arb\_t* n, const *arb\_t* m, const *arb\_t* z, int type, *slong* prec)

void **arb\_hypgeom\_legendre\_q**(*arb\_t* res, const *arb\_t* n, const *arb\_t* m, const *arb\_t* z, int type, *slong* prec)

Computes Legendre functions of the first and second kind. See `acb_hypgeom_legendre_p()` and `acb_hypgeom_legendre_q()` for definitions.

## 7.3 acb\_elliptic.h – elliptic integrals and functions of complex variables

This module supports computation of elliptic (doubly periodic) functions, and their inverses, elliptic integrals. See `acb_modular.h` for the closely related modular forms and Jacobi theta functions.

Warning: incomplete elliptic integrals have very complicated branch structure when extended to complex variables. For some functions in this module, branch cuts may be artifacts of the evaluation algorithm rather than having a natural mathematical justification. The user should, accordingly, watch out for edge cases where the functions implemented here may differ from other systems or literature. There may also exist points where a function should be well-defined but the implemented algorithm fails to produce a finite result due to artificial internal singularities.

### 7.3.1 Complete elliptic integrals

void **acb\_elliptic\_k**(*acb\_t* res, const *acb\_t* m, *slong* prec)  
Computes the complete elliptic integral of the first kind

$$K(m) = \int_0^{\pi/2} \frac{dt}{\sqrt{1 - m \sin^2 t}} = \int_0^1 \frac{dt}{(\sqrt{1 - t^2})(\sqrt{1 - mt^2})}$$

using the arithmetic-geometric mean:  $K(m) = \pi / (2M(\sqrt{1 - m}))$ .

void **acb\_elliptic\_k\_jet**(*acb\_ptr* res, const *acb\_t* m, *slong* len, *slong* prec)  
Sets the coefficients in the array *res* to the power series expansion of the complete elliptic integral of the first kind at the point *m* truncated to length *len*, i.e.  $K(m + x) \in \mathbb{C}[[x]]$ .

void **\_acb\_elliptic\_k\_series**(*acb\_ptr* res, *acb\_srcptr* m, *slong* mlen, *slong* len, *slong* prec)

void **acb\_elliptic\_k\_series**(*acb\_poly\_t* res, const *acb\_poly\_t* m, *slong* len, *slong* prec)  
Sets *res* to the complete elliptic integral of the first kind of the power series *m*, truncated to length *len*.

void **acb\_elliptic\_e**(*acb\_t* res, const *acb\_t* m, *slong* prec)  
Computes the complete elliptic integral of the second kind

$$E(m) = \int_0^{\pi/2} \sqrt{1 - m \sin^2 t} dt = \int_0^1 \frac{\sqrt{1 - mt^2}}{\sqrt{1 - t^2}} dt$$

using  $E(m) = (1 - m)(2mK'(m) + K(m))$  (where the prime denotes a derivative, not a complementary integral).

void **acb\_elliptic\_pi**(*acb\_t* res, const *acb\_t* n, const *acb\_t* m, *slong* prec)  
Evaluates the complete elliptic integral of the third kind

$$\Pi(n, m) = \int_0^{\pi/2} \frac{dt}{(1 - n \sin^2 t) \sqrt{1 - m \sin^2 t}} = \int_0^1 \frac{dt}{(1 - nt^2) \sqrt{1 - t^2} \sqrt{1 - mt^2}}.$$

This implementation currently uses the same algorithm as the corresponding incomplete integral. It is therefore less efficient than the implementations of the first two complete elliptic integrals which use the AGM.

### 7.3.2 Legendre incomplete elliptic integrals

void **acb\_elliptic\_f**(*acb\_t* res, const *acb\_t* phi, const *acb\_t* m, int pi, *slong* prec)  
Evaluates the Legendre incomplete elliptic integral of the first kind, given by

$$F(\phi, m) = \int_0^\phi \frac{dt}{\sqrt{1 - m \sin^2 t}} = \int_0^{\sin \phi} \frac{dt}{(\sqrt{1 - t^2})(\sqrt{1 - mt^2})}$$

on the standard strip  $-\pi/2 \leq \operatorname{Re}(\phi) \leq \pi/2$ . Outside this strip, the function extends quasiperiodically as

$$F(\phi + n\pi, m) = 2nK(m) + F(\phi, m), n \in \mathbb{Z}.$$

Inside the standard strip, the function is computed via the symmetric integral  $R_F$ .

If the flag *pi* is set to 1, the variable  $\phi$  is replaced by  $\pi\phi$ , changing the quasiperiod to 1.

The function reduces to a complete elliptic integral of the first kind when  $\phi = \frac{\pi}{2}$ ; that is,  $F(\frac{\pi}{2}, m) = K(m)$ .

void **acb\_elliptic\_e\_inc**(*acb\_t res*, const *acb\_t phi*, const *acb\_t m*, int *pi*, *slong prec*)  
Evaluates the Legendre incomplete elliptic integral of the second kind, given by

$$E(\phi, m) = \int_0^\phi \sqrt{1 - m \sin^2 t} dt = \int_0^{\sin \phi} \frac{\sqrt{1 - mt^2}}{\sqrt{1 - t^2}} dt$$

on the standard strip  $-\pi/2 \leq \operatorname{Re}(\phi) \leq \pi/2$ . Outside this strip, the function extends quasiperiodically as

$$E(\phi + n\pi, m) = 2nE(m) + E(\phi, m), n \in \mathbb{Z}.$$

Inside the standard strip, the function is computed via the symmetric integrals  $R_F$  and  $R_D$ .

If the flag *pi* is set to 1, the variable  $\phi$  is replaced by  $\pi\phi$ , changing the quasiperiod to 1.

The function reduces to a complete elliptic integral of the second kind when  $\phi = \frac{\pi}{2}$ ; that is,  $E(\frac{\pi}{2}, m) = E(m)$ .

void **acb\_elliptic\_pi\_inc**(*acb\_t res*, const *acb\_t n*, const *acb\_t phi*, const *acb\_t m*, int *pi*, *slong prec*)  
Evaluates the Legendre incomplete elliptic integral of the third kind, given by

$$\Pi(n, \phi, m) = \int_0^\phi \frac{dt}{(1 - n \sin^2 t) \sqrt{1 - m \sin^2 t}} = \int_0^{\sin \phi} \frac{dt}{(1 - nt^2) \sqrt{1 - t^2} \sqrt{1 - mt^2}}$$

on the standard strip  $-\pi/2 \leq \operatorname{Re}(\phi) \leq \pi/2$ . Outside this strip, the function extends quasiperiodically as

$$\Pi(n, \phi + k\pi, m) = 2k\Pi(n, m) + \Pi(n, \phi, m), k \in \mathbb{Z}.$$

Inside the standard strip, the function is computed via the symmetric integrals  $R_F$  and  $R_J$ .

If the flag *pi* is set to 1, the variable  $\phi$  is replaced by  $\pi\phi$ , changing the quasiperiod to 1.

The function reduces to a complete elliptic integral of the third kind when  $\phi = \frac{\pi}{2}$ ; that is,  $\Pi(n, \frac{\pi}{2}, m) = \Pi(n, m)$ .

### 7.3.3 Carlson symmetric elliptic integrals

Carlson symmetric forms are the preferred form of incomplete elliptic integrals, due to their neat properties and relatively simple computation based on duplication theorems. There are five named functions:  $R_F, R_G, R_J$ , and  $R_C, R_D$  which are special cases of  $R_F$  and  $R_J$  respectively. We largely follow the definitions and algorithms in [Car1995] and chapter 19 in [NIST2012].

void **acb\_elliptic\_rf**(*acb\_t res*, const *acb\_t x*, const *acb\_t y*, const *acb\_t z*, int *flags*,  
*slong prec*)

Evaluates the Carlson symmetric elliptic integral of the first kind

$$R_F(x, y, z) = \frac{1}{2} \int_0^\infty \frac{dt}{\sqrt{(t+x)(t+y)(t+z)}}$$

where the square root extends continuously from positive infinity. The integral is well-defined for  $x, y, z \notin (-\infty, 0)$ , and with at most one of  $x, y, z$  being zero. When some parameters are negative real numbers, the function is still defined by analytic continuation.

In general, one or more duplication steps are applied until  $x, y, z$  are close enough to use a multivariate Taylor polynomial of total degree 7.

The special case  $R_C(x, y) = R_F(x, y, y) = \frac{1}{2} \int_0^\infty (t+x)^{-1/2}(t+y)^{-1} dt$  may be computed by setting  $y$  and  $z$  to the same variable. (This case is not yet handled specially, but might be optimized in the future.)

The *flags* parameter is reserved for future use and currently does nothing. Passing 0 results in default behavior.

void **acb\_elliptic\_rg**(*acb\_t res*, const *acb\_t x*, const *acb\_t y*, const *acb\_t z*, int *flags*,  
*slong prec*)

Evaluates the Carlson symmetric elliptic integral of the second kind

$$R_G(x, y, z) = \frac{1}{4} \int_0^\infty \frac{t}{\sqrt{(t+x)(t+y)(t+z)}} \left( \frac{x}{t+x} + \frac{y}{t+y} + \frac{z}{t+z} \right) dt$$

where the square root is taken continuously as in  $R_F$ . The evaluation is done by expressing  $R_G$  in terms of  $R_F$  and  $R_D$ . There are no restrictions on the variables.

void **acb\_elliptic\_rj**(*acb\_t res*, const *acb\_t x*, const *acb\_t y*, const *acb\_t z*, const *acb\_t p*,  
 int *flags*, *slong prec*)

Evaluates the Carlson symmetric elliptic integral of the third kind

$$R_J(x, y, z, p) = \frac{3}{2} \int_0^\infty \frac{dt}{(t+p)\sqrt{(t+x)(t+y)(t+z)}}$$

where the square root is taken continuously as in  $R_F$ .

In general, one or more duplication steps are applied until  $x, y, z, p$  are close enough to use a multivariate Taylor polynomial of total degree 7.

The duplication algorithm is not correct for all possible combinations of complex variables, since the square roots taken during the computation can introduce spurious branch cuts. According to [Car1995], a sufficient (but not necessary) condition for correctness is that  $x, y, z$  have nonnegative real part and that  $p$  has positive real part.

In other cases, the algorithm *might* still be correct, but no attempt is made to check this; it is up to the user to verify that the duplication algorithm is appropriate for the given parameters before calling this function.

The special case  $R_D(x, y, z) = R_J(x, y, z, z)$  may be computed by setting  $z$  and  $p$  to the same variable. This case is handled specially to avoid redundant arithmetic operations. In this case, the algorithm is correct for all  $x, y$  and  $z$ .

The *flags* parameter is reserved for future use and currently does nothing. Passing 0 results in default behavior.

void **acb\_elliptic\_rc1**(*acb\_t res*, const *acb\_t x*, *slong prec*)

This helper function computes the special case  $R_C(1, 1+x) = \text{atan}(\sqrt{x})/\sqrt{x} = {}_2F_1(1, 1/2, 3/2, -x)$ , which is needed in the evaluation of  $R_J$ .

### 7.3.4 Weierstrass elliptic functions

Elliptic functions may be defined on a general lattice  $\Lambda = \{m2\omega_1 + n2\omega_2 : m, n \in \mathbb{Z}\}$  with half-periods  $\omega_1, \omega_2$ . We simplify by setting  $2\omega_1 = 1, 2\omega_2 = \tau$  with  $\text{im}(\tau) > 0$ . To evaluate the functions on a general lattice, it is enough to make a linear change of variables. The main reference is chapter 23 in [NIST2012].

void **acb\_elliptic\_p**(*acb\_t* res, const *acb\_t* z, const *acb\_t* tau, *slong* prec)

Computes Weierstrass's elliptic function

$$\wp(z, \tau) = \frac{1}{z^2} + \sum_{n^2+m^2 \neq 0} \left[ \frac{1}{(z+m+n\tau)^2} - \frac{1}{(m+n\tau)^2} \right]$$

which satisfies  $\wp(z, \tau) = \wp(z+1, \tau) = \wp(z+\tau, \tau)$ . To evaluate the function efficiently, we use the formula

$$\wp(z, \tau) = \pi^2 \theta_2^2(0, \tau) \theta_3^2(0, \tau) \frac{\theta_4^2(z, \tau)}{\theta_1^2(z, \tau)} - \frac{\pi^2}{3} [\theta_3^4(0, \tau) + \theta_4^4(0, \tau)].$$

void **acb\_elliptic\_p\_jet**(*acb\_ptr* res, const *acb\_t* z, const *acb\_t* tau, *slong* len, *slong* prec)

Computes the formal power series  $\wp(z+x, \tau) \in \mathbb{C}[[x]]$ , truncated to length *len*. In particular, with *len* = 2, simultaneously computes  $\wp(z, \tau), \wp'(z, \tau)$  which together generate the field of elliptic functions with periods 1 and  $\tau$ .

void **\_acb\_elliptic\_p\_series**(*acb\_ptr* res, *acb\_srcptr* z, *slong* zlen, const *acb\_t* tau, *slong* len, *slong* prec)

void **acb\_elliptic\_p\_series**(*acb\_poly\_t* res, const *acb\_poly\_t* z, const *acb\_t* tau, *slong* len, *slong* prec)

Sets *res* to the Weierstrass elliptic function of the power series *z*, with periods 1 and *tau*, truncated to length *len*.

void **acb\_elliptic\_invariants**(*acb\_t* g2, *acb\_t* g3, const *acb\_t* tau, *slong* prec)

Computes the lattice invariants  $g_2, g_3$ . The Weierstrass elliptic function satisfies the differential equation  $[\wp'(z, \tau)]^2 = 4[\wp(z, \tau)]^3 - g_2\wp(z, \tau) - g_3$ . Up to constant factors, the lattice invariants are the first two Eisenstein series (see **acb\_modular\_eisenstein()**).

void **acb\_elliptic\_roots**(*acb\_t* e1, *acb\_t* e2, *acb\_t* e3, const *acb\_t* tau, *slong* prec)

Computes the lattice roots  $e_1, e_2, e_3$ , which are the roots of the polynomial  $4z^3 - g_2z - g_3$ .

void **acb\_elliptic\_inv\_p**(*acb\_t* res, const *acb\_t* z, const *acb\_t* tau, *slong* prec)

Computes the inverse of the Weierstrass elliptic function, which satisfies  $\wp(\wp^{-1}(z, \tau), \tau) = z$ . This function is given by the elliptic integral

$$\wp^{-1}(z, \tau) = \frac{1}{2} \int_z^\infty \frac{dt}{\sqrt{(t-e_1)(t-e_2)(t-e_3)}} = R_F(z-e_1, z-e_2, z-e_3).$$

void **acb\_elliptic\_zeta**(*acb\_t* res, const *acb\_t* z, const *acb\_t* tau, *slong* prec)

Computes the Weierstrass zeta function

$$\zeta(z, \tau) = \frac{1}{z} + \sum_{n^2+m^2 \neq 0} \left[ \frac{1}{z-m-n\tau} + \frac{1}{m+n\tau} + \frac{z}{(m+n\tau)^2} \right]$$

which is quasiperiodic with  $\zeta(z+1, \tau) = \zeta(z, \tau) + \zeta(1/2, \tau)$  and  $\zeta(z+\tau, \tau) = \zeta(z, \tau) + \zeta(\tau/2, \tau)$ .

void **acb\_elliptic\_sigma**(*acb\_t* res, const *acb\_t* z, const *acb\_t* tau, *slong* prec)

Computes the Weierstrass sigma function

$$\sigma(z, \tau) = z \prod_{n^2+m^2 \neq 0} \left[ \left( 1 - \frac{z}{m+n\tau} \right) \exp \left( \frac{z}{m+n\tau} + \frac{z^2}{2(m+n\tau)^2} \right) \right]$$

which is quasiperiodic with  $\sigma(z+1, \tau) = -e^{2\zeta(1/2, \tau)(z+1/2)} \sigma(z, \tau)$  and  $\sigma(z+\tau, \tau) = -e^{2\zeta(\tau/2, \tau)(z+\tau/2)} \sigma(z, \tau)$ .

## 7.4 `acb_modular.h` – modular forms of complex variables

This module provides methods for numerical evaluation of modular forms and Jacobi theta functions. See `acb_elliptic.h` for the closely related elliptic functions and integrals.

In the context of this module,  $\tau$  or  $\tau$  always denotes an element of the complex upper half-plane  $\mathbb{H} = \{z \in \mathbb{C} : \text{Im}(z) > 0\}$ . We also often use the variable  $q$ , variously defined as  $q = e^{2\pi i \tau}$  (usually in relation to modular forms) or  $q = e^{\pi i \tau}$  (usually in relation to theta functions) and satisfying  $|q| < 1$ . We will clarify the local meaning of  $q$  every time such a quantity appears as a function of  $\tau$ .

As usual, the numerical functions in this module compute strict error bounds: if  $\tau$  is represented by an `acb_t` whose content overlaps with the real line (or lies in the lower half-plane), and  $\tau$  is passed to a function defined only on  $\mathbb{H}$ , then the output will have an infinite radius. The analogous behavior holds for functions requiring  $|q| < 1$ .

### 7.4.1 The modular group

`psl2z_struct`

`psl2z_t`

Represents an element of the modular group  $\text{PSL}(2, \mathbb{Z})$ , namely an integer matrix

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}$$

with  $ad - bc = 1$ , and with signs canonicalized such that  $c \geq 0$ , and  $d > 0$  if  $c = 0$ . The struct members  $a, b, c, d$  are of type `mpz`.

void `psl2z_init`(`psl2z_t`  $g$ )

Initializes  $g$  and set it to the identity element.

void `psl2z_clear`(`psl2z_t`  $g$ )

Clears  $g$ .

void `psl2z_swap`(`psl2z_t`  $f$ , `psl2z_t`  $g$ )

Swaps  $f$  and  $g$  efficiently.

void `psl2z_set`(`psl2z_t`  $f$ , const `psl2z_t`  $g$ )

Sets  $f$  to a copy of  $g$ .

void `psl2z_one`(`psl2z_t`  $g$ )

Sets  $g$  to the identity element.

int `psl2z_is_one`(const `psl2z_t`  $g$ )

Returns nonzero iff  $g$  is the identity element.

void `psl2z_print`(const `psl2z_t`  $g$ )

Prints  $g$  to standard output.

void `psl2z_fprint`(FILE \*  $file$ , const `psl2z_t`  $g$ )

Prints  $g$  to the stream  $file$ .

int `psl2z_equal`(const `psl2z_t`  $f$ , const `psl2z_t`  $g$ )

Returns nonzero iff  $f$  and  $g$  are equal.

void `psl2z_mul`(`psl2z_t`  $h$ , const `psl2z_t`  $f$ , const `psl2z_t`  $g$ )

Sets  $h$  to the product of  $f$  and  $g$ , namely the matrix product with the signs canonicalized.

void `psl2z_inv`(`psl2z_t`  $h$ , const `psl2z_t`  $g$ )

Sets  $h$  to the inverse of  $g$ .

int `psl2z_is_correct`(const `psl2z_t`  $g$ )

Returns nonzero iff  $g$  contains correct data, i.e. satisfying  $ad - bc = 1$ ,  $c \geq 0$ , and  $d > 0$  if  $c = 0$ .

void **psl2z\_randtest**(*psl2z\_t g*, *flint\_rand\_t state*, *slong bits*)

Sets  $g$  to a random element of  $\mathrm{PSL}(2, \mathbb{Z})$  with entries of bit length at most  $bits$  (or 1, if  $bits$  is not positive). We first generate  $a$  and  $d$ , compute their Bezout coefficients, divide by the GCD, and then correct the signs.

## 7.4.2 Modular transformations

void **acb\_modular\_transform**(*acb\_t w*, const *psl2z\_t g*, const *acb\_t z*, *slong prec*)

Applies the modular transformation  $g$  to the complex number  $z$ , evaluating

$$w = gz = \frac{az + b}{cz + d}.$$

void **acb\_modular\_fundamental\_domain\_approx\_d**(*psl2z\_t g*, double  $x$ , double  $y$ , double *one\_minus\_eps*)

void **acb\_modular\_fundamental\_domain\_approx\_arf**(*psl2z\_t g*, const *arf\_t x*, const *arf\_t y*, const *arf\_t one\_minus\_eps*, *slong prec*)

Attempts to determine a modular transformation  $g$  that maps the complex number  $x + yi$  to the fundamental domain or just slightly outside the fundamental domain, where the target tolerance (not a strict bound) is specified by *one\_minus\_eps*.

The inputs are assumed to be finite numbers, with  $y$  positive.

Uses floating-point iteration, repeatedly applying either the transformation  $z \leftarrow z + b$  or  $z \leftarrow -1/z$ . The iteration is terminated if  $|x| \leq 1/2$  and  $x^2 + y^2 \geq 1 - \varepsilon$  where  $1 - \varepsilon$  is passed as *one\_minus\_eps*. It is also terminated if too many steps have been taken without convergence, or if the numbers end up too large or too small for the working precision.

The algorithm can fail to produce a satisfactory transformation. The output  $g$  is always set to *some* correct modular transformation, but it is up to the user to verify a posteriori that  $g$  maps  $x + yi$  close enough to the fundamental domain.

void **acb\_modular\_fundamental\_domain\_approx**(*acb\_t w*, *psl2z\_t g*, const *acb\_t z*, const *arf\_t one\_minus\_eps*, *slong prec*)

Attempts to determine a modular transformation  $g$  that maps the complex number  $z$  to the fundamental domain or just slightly outside the fundamental domain, where the target tolerance (not a strict bound) is specified by *one\_minus\_eps*. It also computes the transformed value  $w = gz$ .

This function first tries to use **acb\_modular\_fundamental\_domain\_approx\_d**() and checks if the result is acceptable. If this fails, it calls **acb\_modular\_fundamental\_domain\_approx\_arf**() with higher precision. Finally,  $w = gz$  is evaluated by a single application of  $g$ .

The algorithm can fail to produce a satisfactory transformation. The output  $g$  is always set to *some* correct modular transformation, but it is up to the user to verify a posteriori that  $w$  is close enough to the fundamental domain.

int **acb\_modular\_is\_in\_fundamental\_domain**(const *acb\_t z*, const *arf\_t tol*, *slong prec*)

Returns nonzero if it is certainly true that  $|z| \geq 1 - \varepsilon$  and  $|\mathrm{Re}(z)| \leq 1/2 + \varepsilon$  where  $\varepsilon$  is specified by *tol*. Returns zero if this is false or cannot be determined.

## 7.4.3 Addition sequences

void **acb\_modular\_fill\_addseq**(*slong \* tab*, *slong len*)

Builds a near-optimal addition sequence for a sequence of integers which is assumed to be reasonably dense.

As input, the caller should set each entry in *tab* to  $-1$  if that index is to be part of the addition sequence, and to  $0$  otherwise. On output, entry  $i$  in *tab* will either be zero (if the number is not part of the sequence), or a value  $j$  such that both  $j$  and  $i - j$  are also marked. The first two entries in *tab* are ignored (the number 1 is always assumed to be part of the sequence).

## 7.4.4 Jacobi theta functions

Unfortunately, there are many inconsistent notational variations for Jacobi theta functions in the literature. Unless otherwise noted, we use the functions

$$\begin{aligned}\theta_1(z, \tau) &= -i \sum_{n=-\infty}^{\infty} (-1)^n \exp(\pi i[(n+1/2)^2 \tau + (2n+1)z]) = 2q_{1/4} \sum_{n=0}^{\infty} (-1)^n q^{n(n+1)} \sin((2n+1)\pi z) \\ \theta_2(z, \tau) &= \sum_{n=-\infty}^{\infty} \exp(\pi i[(n+1/2)^2 \tau + (2n+1)z]) = 2q_{1/4} \sum_{n=0}^{\infty} q^{n(n+1)} \cos((2n+1)\pi z) \\ \theta_3(z, \tau) &= \sum_{n=-\infty}^{\infty} \exp(\pi i[n^2 \tau + 2nz]) = 1 + 2 \sum_{n=1}^{\infty} q^{n^2} \cos(2n\pi z) \\ \theta_4(z, \tau) &= \sum_{n=-\infty}^{\infty} (-1)^n \exp(\pi i[n^2 \tau + 2nz]) = 1 + 2 \sum_{n=1}^{\infty} (-1)^n q^{n^2} \cos(2n\pi z)\end{aligned}$$

where  $q = \exp(\pi i \tau)$  and  $q_{1/4} = \exp(\pi i \tau / 4)$ . Note that many authors write  $q_{1/4}$  as  $q^{1/4}$ , but the principal fourth root  $(q)^{1/4} = \exp(\frac{1}{4} \log q)$  differs from  $q_{1/4}$  in general and some formulas are only correct if one reads “ $q^{1/4} = \exp(\pi i \tau / 4)$ ”. To avoid confusion, we only write  $q^k$  when  $k$  is an integer.

void **acb\_modular\_theta\_transform**(int \*  $R$ , int \*  $S$ , int \*  $C$ , const *psl2z\_t*  $g$ )

We wish to write a theta function with quasiperiod  $\tau$  in terms of a theta function with quasiperiod  $\tau' = g\tau$ , given some  $g = (a, b; c, d) \in \text{PSL}(2, \mathbb{Z})$ . For  $i = 0, 1, 2, 3$ , this function computes integers  $R_i$  and  $S_i$  ( $R$  and  $S$  should be arrays of length 4) and  $C \in \{0, 1\}$  such that

$$\theta_{1+i}(z, \tau) = \exp(\pi i R_i / 4) \cdot A \cdot B \cdot \theta_{1+S_i}(z', \tau')$$

where  $z' = z$ ,  $A = B = 1$  if  $C = 0$ , and

$$z' = \frac{-z}{c\tau + d}, \quad A = \sqrt{\frac{i}{c\tau + d}}, \quad B = \exp\left(-\pi i c \frac{z^2}{c\tau + d}\right)$$

if  $C = 1$ . Note that  $A$  is well-defined with the principal branch of the square root since  $A^2 = i/(c\tau + d)$  lies in the right half-plane.

Firstly, if  $c = 0$ , we have  $\theta_i(z, \tau) = \exp(-\pi i b/4) \theta_i(z, \tau + b)$  for  $i = 1, 2$ , whereas  $\theta_3$  and  $\theta_4$  remain unchanged when  $b$  is even and swap places with each other when  $b$  is odd. In this case we set  $C = 0$ .

For an arbitrary  $g$  with  $c > 0$ , we set  $C = 1$ . The general transformations are given by Rademacher [Rad1973]. We need the function  $\theta_{m,n}(z, \tau)$  defined for  $m, n \in \mathbb{Z}$  by (beware of the typos in [Rad1973])

$$\theta_{0,0}(z, \tau) = \theta_3(z, \tau), \quad \theta_{0,1}(z, \tau) = \theta_4(z, \tau)$$

$$\theta_{1,0}(z, \tau) = \theta_2(z, \tau), \quad \theta_{1,1}(z, \tau) = i\theta_1(z, \tau)$$

$$\theta_{m+2,n}(z, \tau) = (-1)^n \theta_{m,n}(z, \tau)$$

$$\theta_{m,n+2}(z, \tau) = \theta_{m,n}(z, \tau).$$

Then we may write

$$\begin{aligned}\theta_1(z, \tau) &= \varepsilon_1 AB \theta_1(z', \tau') \\ \theta_2(z, \tau) &= \varepsilon_2 AB \theta_{1-c, 1+a}(z', \tau') \\ \theta_3(z, \tau) &= \varepsilon_3 AB \theta_{1+d-c, 1-b+a}(z', \tau') \\ \theta_4(z, \tau) &= \varepsilon_4 AB \theta_{1+d, 1-b}(z', \tau')\end{aligned}$$

where  $\varepsilon_i$  is an 8th root of unity. Specifically, if we denote the 24th root of unity in the transformation formula of the Dedekind eta function by  $\varepsilon(a, b, c, d) = \exp(\pi i R(a, b, c, d)/12)$  (see `acb_modular_epsilon_arg()`), then:

$$\begin{aligned}\varepsilon_1(a, b, c, d) &= \exp(\pi i [R(-d, b, c, -a) + 1]/4) \\ \varepsilon_2(a, b, c, d) &= \exp(\pi i [-R(a, b, c, d) + (5 + (2 - c)a)]/4) \\ \varepsilon_3(a, b, c, d) &= \exp(\pi i [-R(a, b, c, d) + (4 + (c - d - 2)(b - a))]/4) \\ \varepsilon_4(a, b, c, d) &= \exp(\pi i [-R(a, b, c, d) + (3 - (2 + d)b)]/4)\end{aligned}$$

These formulas are easily derived from the formulas in [Rad1973] (Rademacher has the transformed/untransformed variables exchanged, and his “ $\varepsilon$ ” differs from ours by a constant offset in the phase).

void `acb_modular_addseq_theta`(*slong* \* *exponents*, *slong* \* *aindex*, *slong* \* *bindex*, *slong* *num*)  
 Constructs an addition sequence for the first *num* squares and triangular numbers interleaved (excluding zero), i.e. 1, 2, 4, 6, 9, 12, 16, 20, 25, 30 etc.

void `acb_modular_theta_sum`(*acb\_ptr* *theta1*, *acb\_ptr* *theta2*, *acb\_ptr* *theta3*, *acb\_ptr* *theta4*,  
                               const *acb\_t* *w*, int *w\_is\_unit*, const *acb\_t* *q*, *slong* *len*, *slong* *prec*)  
 Simultaneously computes the first *len* coefficients of each of the formal power series

$$\begin{aligned}\theta_1(z + x, \tau)/q_{1/4} &\in \mathbb{C}[[x]] \\ \theta_2(z + x, \tau)/q_{1/4} &\in \mathbb{C}[[x]] \\ \theta_3(z + x, \tau) &\in \mathbb{C}[[x]] \\ \theta_4(z + x, \tau) &\in \mathbb{C}[[x]]\end{aligned}$$

given  $w = \exp(\pi i z)$  and  $q = \exp(\pi i \tau)$ , by summing a finite truncation of the respective theta function series. In particular, with *len* equal to 1, computes the respective value of the theta function at the point  $z$ . We require *len* to be positive. If *w\_is\_unit* is nonzero,  $w$  is assumed to lie on the unit circle, i.e.  $z$  is assumed to be real.

Note that the factor  $q_{1/4}$  is removed from  $\theta_1$  and  $\theta_2$ . To get the true theta function values, the user has to multiply this factor back. This convention avoids unnecessary computations, since the user can compute  $q_{1/4} = \exp(\pi i \tau/4)$  followed by  $q = (q_{1/4})^4$ , and in many cases when computing products or quotients of theta functions, the factor  $q_{1/4}$  can be eliminated entirely.

This function is intended for  $|q| \ll 1$ . It can be called with any  $q$ , but will return useless intervals if convergence is not rapid. For general evaluation of theta functions, the user should only call this function after applying a suitable modular transformation.

We consider the sums together, alternately updating  $(\theta_1, \theta_2)$  or  $(\theta_3, \theta_4)$ . For  $k = 0, 1, 2, \dots$ , the powers of  $q$  are  $\lfloor (k+2)^2/4 \rfloor = 1, 2, 4, 6, 9$  etc. and the powers of  $w$  are  $\pm(k+2) = \pm 2, \pm 3, \pm 4, \dots$  etc. The scheme is illustrated by the following table:

|         |                      |          |                    |
|---------|----------------------|----------|--------------------|
|         | $\theta_1, \theta_2$ | $q^0$    | $(w^1 \pm w^{-1})$ |
| $k = 0$ | $\theta_3, \theta_4$ | $q^1$    | $(w^2 \pm w^{-2})$ |
| $k = 1$ | $\theta_1, \theta_2$ | $q^2$    | $(w^3 \pm w^{-3})$ |
| $k = 2$ | $\theta_3, \theta_4$ | $q^4$    | $(w^4 \pm w^{-4})$ |
| $k = 3$ | $\theta_1, \theta_2$ | $q^6$    | $(w^5 \pm w^{-5})$ |
| $k = 4$ | $\theta_3, \theta_4$ | $q^9$    | $(w^6 \pm w^{-6})$ |
| $k = 5$ | $\theta_1, \theta_2$ | $q^{12}$ | $(w^7 \pm w^{-7})$ |

For some integer  $N \geq 1$ , the summation is stopped just before term  $k = N$ . Let  $Q = |q|$ ,  $W = \max(|w|, |w^{-1}|)$ ,  $E = \lfloor (N+2)^2/4 \rfloor$  and  $F = \lfloor (N+1)/2 \rfloor + 1$ . The error of the zeroth derivative can be bounded as

$$2Q^E W^{N+2} [1 + Q^F W + Q^{2F} W^2 + \dots] = \frac{2Q^E W^{N+2}}{1 - Q^F W}$$

provided that the denominator is positive (otherwise we set the error bound to infinity). When *len* is greater than 1, consider the derivative of order  $r$ . The term of index  $k$  and order  $r$  picks up a

factor of magnitude  $(k+2)^r$  from differentiation of  $w^{k+2}$  (it also picks up a factor  $\pi^r$ , but we omit this until we rescale the coefficients at the end of the computation). Thus we have the error bound

$$2Q^E W^{N+2} (N+2)^r \left[ 1 + Q^F W \frac{(N+3)^r}{(N+2)^r} + Q^{2F} W^2 \frac{(N+4)^r}{(N+2)^r} + \dots \right]$$

which by the inequality  $(1 + m/(N+2))^r \leq \exp(mr/(N+2))$  can be bounded as

$$\frac{2Q^E W^{N+2} (N+2)^r}{1 - Q^F W \exp(r/(N+2))},$$

again valid when the denominator is positive.

To actually evaluate the series, we write the even cosine terms as  $w^{2n} + w^{-2n}$ , the odd cosine terms as  $w(w^{2n} + w^{-2n-2})$ , and the sine terms as  $w(w^{2n} - w^{-2n-2})$ . This way we only need even powers of  $w$  and  $w^{-1}$ . The implementation is not yet optimized for real  $z$ , in which case further work can be saved.

This function does not permit aliasing between input and output arguments.

```
void acb_modular_theta_const_sum_basecase(acb_t theta2, acb_t theta3, acb_t theta4, const
                                          acb_t q, slong N, slong prec)
```

```
void acb_modular_theta_const_sum_rs(acb_t theta2, acb_t theta3, acb_t theta4, const acb_t q,
                                    slong N, slong prec)
```

Computes the truncated theta constant sums  $\theta_2 = \sum_{k(k+1) < N} q^{k(k+1)}$ ,  $\theta_3 = \sum_{k^2 < N} q^{k^2}$ ,  $\theta_4 = \sum_{k^2 < N} (-1)^k q^{k^2}$ . The *basecase* version uses a short addition sequence. The *rs* version uses rectangular splitting. The algorithms are described in [EHJ2016].

```
void acb_modular_theta_const_sum(acb_t theta2, acb_t theta3, acb_t theta4, const acb_t q,
                                 slong prec)
```

Computes the respective theta constants by direct summation (without applying modular transformations). This function selects an appropriate  $N$ , calls either `acb_modular_theta_const_sum_basecase()` or `acb_modular_theta_const_sum_rs()` or depending on  $N$ , and adds a bound for the truncation error.

```
void acb_modular_theta_notransform(acb_t theta1, acb_t theta2, acb_t theta3, acb_t theta4,
                                  const acb_t z, const acb_t tau, slong prec)
```

Evaluates the Jacobi theta functions  $\theta_i(z, \tau)$ ,  $i = 1, 2, 3, 4$  simultaneously. This function does not move  $\tau$  to the fundamental domain. This is generally worse than `acb_modular_theta()`, but can be slightly better for moderate input.

```
void acb_modular_theta(acb_t theta1, acb_t theta2, acb_t theta3, acb_t theta4, const acb_t z,
                      const acb_t tau, slong prec)
```

Evaluates the Jacobi theta functions  $\theta_i(z, \tau)$ ,  $i = 1, 2, 3, 4$  simultaneously. This function moves  $\tau$  to the fundamental domain before calling `acb_modular_theta_sum()`.

```
void acb_modular_theta_jet_notransform(acb_ptr theta1, acb_ptr theta2, acb_ptr theta3,
                                       acb_ptr theta4, const acb_t z, const acb_t tau,
                                       slong len, slong prec)
```

```
void acb_modular_theta_jet(acb_ptr theta1, acb_ptr theta2, acb_ptr theta3, acb_ptr theta4,
                           const acb_t z, const acb_t tau, slong len, slong prec)
```

Evaluates the Jacobi theta functions along with their derivatives with respect to  $z$ , writing the first *len* coefficients in the power series  $\theta_i(z + x, \tau) \in \mathbb{C}[[x]]$  to each respective output variable. The *notransform* version does not move  $\tau$  to the fundamental domain during the computation.

## 7.4.5 The Dedekind eta function

```
void acb_modular_addseq_eta(slong * exponents, slong * aindex, slong * bindex, slong num)
```

Constructs an addition sequence for the first *num* generalized pentagonal numbers (excluding zero), i.e. 1, 2, 5, 7, 12, 15, 22, 26, 35, 40 etc.

void **acb\_modular\_eta\_sum**(*acb\_t eta*, const *acb\_t q*, *slong prec*)  
 Evaluates the Dedekind eta function without the leading 24th root, i.e.

$$\exp(-\pi i \tau / 12) \eta(\tau) = \sum_{n=-\infty}^{\infty} (-1)^n q^{(3n^2-n)/2}$$

given  $q = \exp(2\pi i \tau)$ , by summing the defining series.

This function is intended for  $|q| \ll 1$ . It can be called with any  $q$ , but will return useless intervals if convergence is not rapid. For general evaluation of the eta function, the user should only call this function after applying a suitable modular transformation.

The series is evaluated using either a short addition sequence or rectangular splitting, depending on the number of terms. The algorithms are described in [EHJ2016].

int **acb\_modular\_epsilon\_arg**(const *psl2z\_t g*)  
 Given  $g = (a, b; c, d)$ , computes an integer  $R$  such that  $\varepsilon(a, b, c, d) = \exp(\pi i R / 12)$  is the 24th root of unity in the transformation formula for the Dedekind eta function,

$$\eta\left(\frac{a\tau + b}{c\tau + d}\right) = \varepsilon(a, b, c, d) \sqrt{c\tau + d} \eta(\tau).$$

void **acb\_modular\_eta**(*acb\_t r*, const *acb\_t tau*, *slong prec*)  
 Computes the Dedekind eta function  $\eta(\tau)$  given  $\tau$  in the upper half-plane. This function applies the functional equation to move  $\tau$  to the fundamental domain before calling *acb\_modular\_eta\_sum()*.

## 7.4.6 Modular forms

void **acb\_modular\_j**(*acb\_t r*, const *acb\_t tau*, *slong prec*)  
 Computes Klein's j-invariant  $j(\tau)$  given  $\tau$  in the upper half-plane. The function is normalized so that  $j(i) = 1728$ . We first move  $\tau$  to the fundamental domain, which does not change the value of the function. Then we use the formula  $j(\tau) = 32(\theta_2^8 + \theta_3^8 + \theta_4^8)^3 / (\theta_2 \theta_3 \theta_4)^8$  where  $\theta_i = \theta_i(0, \tau)$ .

void **acb\_modular\_lambda**(*acb\_t r*, const *acb\_t tau*, *slong prec*)  
 Computes the lambda function  $\lambda(\tau) = \theta_2^4(0, \tau) / \theta_3^4(0, \tau)$ , which is invariant under modular transformations  $(a, b; c, d)$  where  $a, d$  are odd and  $b, c$  are even.

void **acb\_modular\_delta**(*acb\_t r*, const *acb\_t tau*, *slong prec*)  
 Computes the modular discriminant  $\Delta(\tau) = \eta(\tau)^{24}$ , which transforms as

$$\Delta\left(\frac{a\tau + b}{c\tau + d}\right) = (c\tau + d)^{12} \Delta(\tau).$$

The modular discriminant is sometimes defined with an extra factor  $(2\pi)^{12}$ , which we omit in this implementation.

void **acb\_modular\_eisenstein**(*acb\_ptr r*, const *acb\_t tau*, *slong len*, *slong prec*)  
 Computes simultaneously the first *len* entries in the sequence of Eisenstein series  $G_4(\tau), G_6(\tau), G_8(\tau), \dots$ , defined by

$$G_{2k}(\tau) = \sum_{m^2 + n^2 \neq 0} \frac{1}{(m + n\tau)^{2k}}$$

and satisfying

$$G_{2k}\left(\frac{a\tau + b}{c\tau + d}\right) = (c\tau + d)^{2k} G_{2k}(\tau).$$

We first evaluate  $G_4(\tau)$  and  $G_6(\tau)$  on the fundamental domain using theta functions, and then compute the Eisenstein series of higher index using a recurrence relation.

### 7.4.7 Elliptic integrals and functions

See the [acb\\_elliptic.h](#) module for elliptic integrals and functions. The following wrappers are available for backwards compatibility.

```
void acb_modular_elliptic_k(acb_t w, const acb_t m, slong prec)
void acb_modular_elliptic_k_cpx(acb_ptr w, const acb_t m, slong len, slong prec)
void acb_modular_elliptic_e(acb_t w, const acb_t m, slong prec)
void acb_modular_elliptic_p(acb_t wp, const acb_t z, const acb_t tau, slong prec)
void acb_modular_elliptic_p_zpx(acb_ptr wp, const acb_t z, const acb_t tau, slong len,
                                slong prec)
```

### 7.4.8 Class polynomials

```
void acb_modular_hilbert_class_poly(fmpz_poly_t res, slong D)
    Sets res to the Hilbert class polynomial of discriminant D, defined as
```

$$H_D(x) = \prod_{(a,b,c)} \left( x - j \left( \frac{-b + \sqrt{D}}{2a} \right) \right)$$

where  $(a, b, c)$  ranges over the primitive reduced positive definite binary quadratic forms of discriminant  $b^2 - 4ac = D$ .

The Hilbert class polynomial is only defined if  $D < 0$  and  $D$  is congruent to 0 or 1 mod 4. If some other value of  $D$  is passed as input, *res* is set to the zero polynomial.

## 7.5 dirichlet.h – Dirichlet characters

*Warning: the interfaces in this module are experimental and may change without notice.*

This module allows working with Dirichlet characters algebraically. For evaluations of characters as complex numbers, see [acb\\_dirichlet.h – Dirichlet L-functions, zeta functions, and related functions](#).

### 7.5.1 Dirichlet characters

Working with Dirichlet characters mod  $q$  consists mainly in going from residue classes mod  $q$  to exponents on a set of generators of the group.

This implementation relies on the Conrey numbering scheme introduced in the [L-functions and Modular Forms DataBase](#), which is an explicit choice of generators allowing to represent Dirichlet characters via the pairing

$$\begin{array}{ccccc} (\mathbb{Z}/q\mathbb{Z})^\times \times (\mathbb{Z}/q\mathbb{Z})^\times & \rightarrow & \bigoplus_i \mathbb{Z}/\phi_i\mathbb{Z} \times \mathbb{Z}/\phi_i\mathbb{Z} & \rightarrow & \mathbb{C} \\ (m, n) & \mapsto & (a_i, b_i) & \mapsto & \chi_q(m, n) = \exp(2i\pi \sum \frac{a_i b_i}{\phi_i}) \end{array}$$

We call *number* a residue class  $m$  modulo  $q$ , and *log* the corresponding vector  $(a_i)$  of exponents of Conrey generators.

Going from a *log* to the corresponding *number* is a cheap operation we call exponential, while the converse requires computing discrete logarithms.

## 7.5.2 Multiplicative group modulo $q$

`dirichlet_group_struct`

`dirichlet_group_t`

Represents the group of Dirichlet characters mod  $q$ .

An `dirichlet_group_t` is defined as an array of `dirichlet_group_struct` of length 1, permitting it to be passed by reference.

void `dirichlet_group_init`(`dirichlet_group_t`  $G$ , `ulong`  $q$ )

Initializes  $G$  to the group of Dirichlet characters mod  $q$ .

This method computes a canonical decomposition of  $G$  in terms of cyclic groups, which are the mod  $p^e$  subgroups for  $p^e \parallel q$ , plus the specific generator described by Conrey for each subgroup.

In particular  $G$  contains:

- the number *num* of components
- the generators
- the exponent *expo* of the group

It does *not* automatically precompute lookup tables of discrete logarithms or numerical roots of unity, and can therefore safely be called even with large  $q$ .

For implementation reasons, the largest prime factor of  $q$  must not exceed  $10^{12}$  (an abort will be raised). This restriction could be removed in the future.

void `dirichlet_subgroup_init`(`dirichlet_group_t`  $H$ , const `dirichlet_group_t`  $G$ , `ulong`  $h$ )

Given an already computed group  $G$  mod  $q$ , initialize its subgroup  $H$  defined mod  $h \mid q$ . Precomputed discrete log tables are inherited.

void `dirichlet_group_clear`(`dirichlet_group_t`  $G$ )

Clears  $G$ . Remark this function does *not* clear the discrete logarithm tables stored in  $G$  (which may be shared with another group).

`ulong` `dirichlet_group_size`(const `dirichlet_group_t`  $G$ )

Returns the number of elements in  $G$ , i.e.  $\varphi(q)$ .

`ulong` `dirichlet_group_num_primitive`(const `dirichlet_group_t`  $G$ )

Returns the number of primitive elements in  $G$ .

void `dirichlet_group_dlog_precompute`(`dirichlet_group_t`  $G$ , `ulong`  $num$ )

Precompute decomposition and tables for discrete log computations in  $G$ , so as to minimize the complexity of  $num$  calls to discrete logarithms.

If  $num$  gets very large, the entire group may be indexed.

void `dirichlet_group_dlog_clear`(`dirichlet_group_t`  $G$ , `ulong`  $num$ )

Clear discrete logarithm tables in  $G$ . When discrete logarithm tables are shared with subgroups, those subgroups must be cleared before clearing the tables.

## 7.5.3 Character type

`dirichlet_char_struct`

`dirichlet_char_t`

Represents a Dirichlet character. This structure contains both a *number* (residue class) and the corresponding *log* (exponents on the group generators).

An `dirichlet_char_t` is defined as an array of `dirichlet_char_struct` of length 1, permitting it to be passed by reference.

void `dirichlet_char_init`(`dirichlet_char_t`  $chi$ , const `dirichlet_group_t`  $G$ )

Initializes  $chi$  to an element of the group  $G$  and sets its value to the principal character.

---

```
void dirichlet_char_clear(dirichlet_char_t chi)
    Clears chi.
```

```
void dirichlet_char_print(const dirichlet_group_t G, const dirichlet_char_t chi)
    Prints the array of exponents representing this character.
```

```
void dirichlet_char_log(dirichlet_char_t x, const dirichlet_group_t G, ulong m)
    Sets x to the character of number m, computing its log using discrete logarithm in G.
```

```
ulong dirichlet_char_exp(const dirichlet_group_t G, const dirichlet_char_t x)
    Returns the number m corresponding to exponents in x.
```

```
ulong _dirichlet_char_exp(dirichlet_char_t x, const dirichlet_group_t G)
    Computes and returns the number m corresponding to exponents in x. This function is for internal
    use.
```

```
void dirichlet_char_one(dirichlet_char_t x, const dirichlet_group_t G)
    Sets x to the principal character in G, having  $\log [0, \dots 0]$ .
```

```
void dirichlet_char_first_primitive(dirichlet_char_t x, const dirichlet_group_t G)
    Sets x to the first primitive character of G, having  $\log [1, \dots 1]$ , or  $[0, 1, \dots 1]$  if  $8 \mid q$ .
```

```
void dirichlet_char_set(dirichlet_char_t x, const dirichlet_group_t G, const dirich-
    let_char_t y)
    Sets x to the element y.
```

```
int dirichlet_char_next(dirichlet_char_t x, const dirichlet_group_t G)
    Sets x to the next character in G according to lexicographic ordering of  $\log$ .

    The return value is the index of the last updated exponent of x, or -1 if the last element has been
    reached.

    This function allows to iterate on all elements of G looping on their  $\log$ . Note that it produces
    elements in seemingly random number order.

    The following template can be used for such a loop:
```

```
dirichlet_char_one(chi, G);
do {
    /* use character chi */
} while (dirichlet_char_next(chi, G) >= 0);
```

```
int dirichlet_char_next_primitive(dirichlet_char_t x, const dirichlet_group_t G)
    Same as dirichlet_char_next(), but jumps to the next primitive character of G.
```

```
ulong dirichlet_index_char(const dirichlet_group_t G, const dirichlet_char_t x)
    Returns the lexicographic index of the  $\log$  of x as an integer in  $0 \dots \varphi(q)$ .
```

```
void dirichlet_char_index(dirichlet_char_t x, const dirichlet_group_t G, ulong j)
    Sets x to the character whose  $\log$  has lexicographic index j.
```

```
int dirichlet_char_eq(const dirichlet_char_t x, const dirichlet_char_t y)
    Return 1 if x equals y.
```

```
int dirichlet_char_eq_deep(const dirichlet_group_t G, const dirichlet_char_t x, const dirich-
    let_char_t y)
    Return 1 if x equals y.

    The second version checks every byte of the representation and is intended for testing only.
```

## 7.5.4 Character properties

As a consequence of the Conrey numbering, all these numbers are available at the level of *number* and *char* object. Both case require no discrete log computation.

```
int dirichlet_char_is_principal(const dirichlet_group_t G, const dirichlet_char_t chi)
    Returns 1 if chi is the principal character mod q.
```

`ulong dirichlet_conductor_ui(const dirichlet_group_t G, ulong a)`

`ulong dirichlet_conductor_char(const dirichlet_group_t G, const dirichlet_char_t x)`  
Returns the *conductor* of  $\chi_q(a, \cdot)$ , that is the smallest  $r$  dividing  $q$  such  $\chi_q(a, \cdot)$  can be obtained as a character mod  $r$ .

`int dirichlet_parity_ui(const dirichlet_group_t G, ulong a)`

`int dirichlet_parity_char(const dirichlet_group_t G, const dirichlet_char_t x)`  
Returns the *parity*  $\lambda$  in  $\{0, 1\}$  of  $\chi_q(a, \cdot)$ , such that  $\chi_q(a, -1) = (-1)^\lambda$ .

`ulong dirichlet_order_ui(const dirichlet_group_t G, ulong a)`

`ulong dirichlet_order_char(const dirichlet_group_t G, const dirichlet_char_t x)`  
Returns the order of  $\chi_q(a, \cdot)$  which is the order of  $a$  mod  $q$ .

`int dirichlet_char_is_real(const dirichlet_group_t G, const dirichlet_char_t chi)`  
Returns 1 if *chi* is a real character (iff it has order  $\leq 2$ ).

`int dirichlet_char_is_primitive(const dirichlet_group_t G, const dirichlet_char_t chi)`  
Returns 1 if *chi* is primitive (iff its conductor is exactly  $q$ ).

## 7.5.5 Character evaluation

Dirichlet characters take value in a finite cyclic group of roots of unity plus zero.

Evaluation functions return a *ulong*, this number corresponds to the power of a primitive root of unity, the special value `DIRICHLET_CHI_NULL` encoding the zero value.

`ulong dirichlet_pairing(const dirichlet_group_t G, ulong m, ulong n)`

`ulong dirichlet_pairing_char(const dirichlet_group_t G, const dirichlet_char_t chi, const dirichlet_char_t psi)`  
Compute the value of the Dirichlet pairing on numbers  $m$  and  $n$ , as exponent modulo  $G \rightarrow expo$ .  
The *char* variant takes as input two characters, so that no discrete logarithm is computed.  
The returned value is the numerator of the actual value exponent mod the group exponent  $G \rightarrow expo$ .

`ulong dirichlet_chi(const dirichlet_group_t G, const dirichlet_char_t chi, ulong n)`  
Compute the value  $\chi(n)$  as the exponent modulo  $G \rightarrow expo$ .

`void dirichlet_chi_vec(ulong * v, const dirichlet_group_t G, const dirichlet_char_t chi, slong nv)`  
Compute the list of exponent values  $v[k]$  for  $0 \leq k < nv$ , as exponents modulo  $G \rightarrow expo$ .

`void dirichlet_chi_vec_order(ulong * v, const dirichlet_group_t G, const dirichlet_char_t chi, ulong order, slong nv)`  
Compute the list of exponent values  $v[k]$  for  $0 \leq k < nv$ , as exponents modulo *order*, which is assumed to be a multiple of the order of *chi*.

## 7.5.6 Character operations

`void dirichlet_char_mul(dirichlet_char_t chi12, const dirichlet_group_t G, const dirichlet_char_t chi1, const dirichlet_char_t chi2)`  
Multiply two characters of the same group  $G$ .

`void dirichlet_char_pow(dirichlet_char_t c, const dirichlet_group_t G, const dirichlet_char_t a, ulong n)`  
Take the power of a character.

`void dirichlet_char_lift(dirichlet_char_t chi_G, const dirichlet_group_t G, const dirichlet_char_t chi_H, const dirichlet_group_t H)`  
If  $H$  is a subgroup of  $G$ , computes the character in  $G$  corresponding to  $chi_H$  in  $H$ .

void **dirichlet\_char\_lower**(*dirichlet\_char\_t* *chi\_H*, const *dirichlet\_group\_t* *H*, const *dirichlet\_char\_t* *chi\_G*, const *dirichlet\_group\_t* *G*)  
 If *chi\_G* is a character of *G* which factors through *H*, sets *chi\_H* to the corresponding restriction in *H*.  
 This requires  $c(\chi_G) \mid q_H \mid q_G$ , where  $c(\chi_G)$  is the conductor of  $\chi_G$  and  $q_G, q_H$  are the moduli of *G* and *H*.

## 7.6 acb\_dirichlet.h – Dirichlet L-functions, zeta functions, and related functions

*Warning: the interfaces in this module are experimental and may change without notice.*

This module allows working with values of Dirichlet characters, Dirichlet L-functions, and related functions. Working with Dirichlet characters is documented in [dirichlet.h – Dirichlet characters](#).

A Dirichlet L-function is the analytic continuation of an L-series

$$L(s, \chi) = \sum_{k=1}^{\infty} \frac{\chi(k)}{k^s}$$

where  $\chi(k)$  is a Dirichlet character.

The code in other modules for computing the Riemann zeta function, Hurwitz zeta function and polylogarithm will possibly be migrated to this module in the future.

### 7.6.1 Roots of unity

**acb\_dirichlet\_roots\_struct**

**acb\_dirichlet\_roots\_t**

void **acb\_dirichlet\_roots\_init**(*acb\_dirichlet\_roots\_t* *roots*, *ulong* *n*, *slong* *num*, *slong* *prec*)  
 Initializes *roots* with precomputed data for fast evaluation of roots of unity  $e^{2\pi i k/n}$  of a fixed order *n*. The precomputation is optimized for *num* evaluations.

For very small *num*, only the single root  $e^{2\pi i/n}$  will be precomputed, which can then be raised to a power. For small *prec* and large *n*, this method might even skip precomputing this single root if it estimates that evaluating roots of unity from scratch will be faster than powering.

If *num* is large enough, the whole set of roots in the first quadrant will be precomputed at once. However, this is automatically avoided for large *n* if too much memory would be used. For intermediate *num*, baby-step giant-step tables are computed.

void **acb\_dirichlet\_roots\_clear**(*acb\_dirichlet\_roots\_t* *roots*)  
 Clears the structure.

void **acb\_dirichlet\_root**(*acb\_t* *res*, const *acb\_dirichlet\_roots\_t* *roots*, *ulong* *k*, *slong* *prec*)  
 Computes  $e^{2\pi i k/n}$ .

### 7.6.2 Truncated L-series and power sums

void **acb\_dirichlet\_powsum\_term**(*acb\_ptr* *res*, *arb\_t* *log\_prev*, *ulong* \* *prev*, const *acb\_t* *s*, *ulong* *k*, int *integer*, int *critical\_line*, *slong* *len*, *slong* *prec*)  
 Sets *res* to  $k^{-(s+x)}$  as a power series in *x* truncated to length *len*. The flags *integer* and *critical\_line* respectively specify optimizing for *s* being an integer or having real part 1/2.

On input *log\_prev* should contain the natural logarithm of the integer at *prev*. If *prev* is close to *k*, this can be used to speed up computations. If  $\log(k)$  is computed internally by this function, then *log\_prev* is overwritten by this value, and the integer at *prev* is overwritten by *k*, allowing *log\_prev* to be recycled for the next term when evaluating a power sum.

void **acb\_dirichlet\_powsum\_sieved**(*acb\_ptr* res, const *acb\_t* s, *ulong* n, *slong* len, *slong* prec)  
Sets *res* to  $\sum_{k=1}^n k^{-(s+x)}$  as a power series in  $x$  truncated to length *len*. This function stores a table of powers that have already been calculated, computing  $(ij)^r$  as  $i^r j^r$  whenever  $k = ij$  is composite. As a further optimization, it groups all even  $k$  and evaluates the sum as a polynomial in  $2^{-(s+x)}$ . This scheme requires about  $n/\log n$  powers,  $n/2$  multiplications, and temporary storage of  $n/6$  power series. Due to the extra power series multiplications, it is only faster than the naive algorithm when *len* is small.

void **acb\_dirichlet\_powsum\_smooth**(*acb\_ptr* res, const *acb\_t* s, *ulong* n, *slong* len, *slong* prec)  
Sets *res* to  $\sum_{k=1}^n k^{-(s+x)}$  as a power series in  $x$  truncated to length *len*. This function performs partial sieving by adding multiples of 5-smooth  $k$  into separate buckets. Asymptotically, this requires computing 4/15 of the powers, which is slower than *sieved*, but only requires logarithmic extra space. It is also faster for large *len*, since most power series multiplications are traded for additions. A slightly bigger gain for larger  $n$  could be achieved by using more small prime factors, at the expense of space.

### 7.6.3 Riemann zeta function and Riemann-Siegel formula

The Riemann-Siegel (RS) formula is implemented closely following J. Arias de Reyna [Ari2011]. For  $s = \sigma + it$  with  $t > 0$ , the expansion takes the form

$$\zeta(s) = \mathcal{R}(s) + X(s)\overline{\mathcal{R}}(1-s), \quad X(s) = \pi^{s-1/2} \frac{\Gamma((1-s)/2)}{\Gamma(s/2)}$$

where

$$\mathcal{R}(s) = \sum_{k=1}^N \frac{1}{k^s} + (-1)^{N-1} U a^{-\sigma} \left[ \sum_{k=0}^K \frac{C_k(p)}{a^k} + RS_K \right]$$

$$U = \exp \left( -i \left[ \frac{t}{2} \log \left( \frac{t}{2\pi} \right) - \frac{t}{2} - \frac{\pi}{8} \right] \right), \quad a = \sqrt{\frac{t}{2\pi}}, \quad N = \lfloor a \rfloor, \quad p = 1 - 2(a - N).$$

The coefficients  $C_k(p)$  in the asymptotic part of the expansion are expressed in terms of certain auxiliary coefficients  $d_j^{(k)}$  and  $F^{(j)}(p)$ . Because of artificial discontinuities,  $s$  should be exact inside the evaluation.

void **acb\_dirichlet\_zeta\_rs\_f\_coeffs**(*acb\_ptr* f, const *arb\_t* p, *slong* n, *slong* prec)  
Computes the coefficients  $F^{(j)}(p)$  for  $0 \leq j < n$ . Uses power series division. This method breaks down when  $p = \pm 1/2$  (which is not problem if  $s$  is an exact floating-point number).

void **acb\_dirichlet\_zeta\_rs\_d\_coeffs**(*arb\_ptr* d, const *arb\_t* sigma, *slong* k, *slong* prec)  
Computes the coefficients  $d_j^{(k)}$  for  $0 \leq j \leq \lfloor 3k/2 \rfloor + 1$ . On input, the array *d* must contain the coefficients for  $d_j^{(k-1)}$  unless  $k = 0$ , and these coefficients will be updated in-place.

void **acb\_dirichlet\_zeta\_rs\_bound**(*mag\_t* err, const *acb\_t* s, *slong* K)  
Bounds the error term  $RS_K$  following Theorem 4.2 in Arias de Reyna.

void **acb\_dirichlet\_zeta\_rs\_r**(*acb\_t* res, const *acb\_t* s, *slong* K, *slong* prec)  
Computes  $\mathcal{R}(s)$  in the upper half plane. Uses precisely  $K$  asymptotic terms in the RS formula if this input parameter is positive; otherwise chooses the number of terms automatically based on  $s$  and the precision.

void **acb\_dirichlet\_zeta\_rs**(*acb\_t* res, const *acb\_t* s, *slong* K, *slong* prec)  
Computes  $\zeta(s)$  using the Riemann-Siegel formula. Uses precisely  $K$  asymptotic terms in the RS formula if this input parameter is positive; otherwise chooses the number of terms automatically based on  $s$  and the precision.

void **acb\_dirichlet\_zeta**(*acb\_t* res, const *acb\_t* s, *slong* prec)  
Computes  $\zeta(s)$  using an automatic choice of algorithm.

void **acb\_dirichlet\_zeta\_bound**(*mag\_t* res, const *acb\_t* s)

Computes an upper bound for  $|\zeta(s)|$  quickly. On the critical strip (and slightly outside of it), formula (43.3) in [Rad1973] is used. To the right, evaluating at the real part of  $s$  gives a trivial bound. To the left, the functional equation is used.

void **acb\_dirichlet\_eta**(*acb\_t* res, const *acb\_t* s, *slong* prec)

Sets *res* to the Dirichlet eta function  $\eta(s) = \sum_{k=1}^{\infty} (-1)^k / k^s = (1 - 2^{1-s})\zeta(s)$ , also known as the alternating zeta function. Note that the alternating character  $\{1, -1\}$  is not itself a Dirichlet character.

### 7.6.4 Hurwitz zeta function

void **acb\_dirichlet\_hurwitz**(*acb\_t* res, const *acb\_t* s, const *acb\_t* a, *slong* prec)

Computes the Hurwitz zeta function  $\zeta(s, a)$ . This function automatically delegates to the code for the Riemann zeta function when  $a = 1$ . Some other special cases may also be handled by direct formulas. In general, Euler-Maclaurin summation is used.

### 7.6.5 Hurwitz zeta function precomputation

**acb\_dirichlet\_hurwitz\_precomp\_struct**

**acb\_dirichlet\_hurwitz\_precomp\_t**

void **acb\_dirichlet\_hurwitz\_precomp\_init**(*acb\_dirichlet\_hurwitz\_precomp\_t* pre, const *acb\_t* s, int deflate, *ulong* A, *ulong* K, *ulong* N, *slong* prec)

Precomputes a grid of Taylor polynomials for fast evaluation of  $\zeta(s, a)$  on  $a \in (0, 1]$  with fixed  $s$ .  $A$  is the initial shift to apply to  $a$ ,  $K$  is the number of Taylor terms,  $N$  is the number of grid points. The precomputation requires  $NK$  evaluations of the Hurwitz zeta function, and each subsequent evaluation requires  $2K$  simple arithmetic operations (polynomial evaluation) plus  $A$  powers. As  $K$  grows, the error is at most  $O(1/(2AN)^K)$ .

We require that  $A$ ,  $K$  and  $N$  are all positive. Moreover, for a finite error bound, we require  $K + \text{re}(s) > 1$ . To avoid an initial “bump” that steals precision and slows convergence,  $AN$  should be at least roughly as large as  $|s|$ , e.g. it is a good idea to have at least  $AN > 0.5|s|$ .

If *deflate* is set, the deflated Hurwitz zeta function is used, removing the pole at  $s = 1$ .

void **acb\_dirichlet\_hurwitz\_precomp\_clear**(*acb\_dirichlet\_hurwitz\_precomp\_t* pre)

Clears the precomputed data.

void **acb\_dirichlet\_hurwitz\_precomp\_choose\_param**(*ulong* \* A, *ulong* \* K, *ulong* \* N, const *acb\_t* s, double num\_eval, *slong* prec)

Chooses precomputation parameters  $A$ ,  $K$  and  $N$  to minimize the cost of *num\_eval* evaluations of the Hurwitz zeta function at argument  $s$  to precision *prec*. If it is estimated that evaluating each Hurwitz zeta function from scratch would be better than performing a precomputation,  $A$ ,  $K$  and  $N$  are all set to 0.

void **acb\_dirichlet\_hurwitz\_precomp\_bound**(*mag\_t* res, const *acb\_t* s, *ulong* A, *ulong* K, *ulong* N)

Computes an upper bound for the truncation error (not accounting for roundoff error) when evaluating  $\zeta(s, a)$  with precomputation parameters  $A$ ,  $K$ ,  $N$ , assuming that  $0 < a \leq 1$ . For details, see *Algorithms for the Hurwitz zeta function*.

void **acb\_dirichlet\_hurwitz\_precomp\_eval**(*acb\_t* res, const *acb\_dirichlet\_hurwitz\_precomp\_t* pre, *ulong* p, *ulong* q, *slong* prec)

Evaluates  $\zeta(s, p/q)$  using precomputed data, assuming that  $0 < p/q \leq 1$ .

```
void acb_dirichlet_jacobi_sum(acb_t res, const dirichlet_group_t G, const dirichlet_char_t chi1, const dirichlet_char_t chi2, slong prec)
void acb_dirichlet_jacobi_sum_ui(acb_t res, const dirichlet_group_t G, ulong a, ulong b, slong prec)
```

Computes the Jacobi sum

$$J_q(a, b) = \sum_{x \bmod q} \chi_q(a, x) \chi_q(b, 1 - x)$$

- the *naive* version computes the sum as defined.
- the *factor* version writes it as a product of local Jacobi sums
- the *gauss* version assumes  $ab$  is primitive and uses the formula  $J_q(a, b)G_q(ab) = G_q(a)G_q(b)$
- the default version automatically combines the above methods.
- the *ui* version only takes the Conrey numbers  $a$  and  $b$  as parameters.

```
void acb_dirichlet_chi_theta_arb(acb_t res, const dirichlet_group_t G, const dirichlet_char_t chi, const arb_t t, slong prec)
void acb_dirichlet_ui_theta_arb(acb_t res, const dirichlet_group_t G, ulong a, const arb_t t, slong prec)
```

Compute the theta series  $\Theta_q(a, t)$  for real argument  $t > 0$ . Beware that if  $t < 1$  the functional equation

$$t\theta(a, t) = \epsilon(\chi)\theta\left(\frac{1}{a}, \frac{1}{t}\right)$$

should be used, which is not done automatically (to avoid recomputing the Gauss sum).

We call *theta series* of a Dirichlet character the quadratic series

$$\Theta_q(a) = \sum_{n \geq 0} \chi_q(a, n) n^p x^{n^2}$$

where  $p$  is the parity of the character  $\chi_q(a, \cdot)$ .

For  $\Re(t) > 0$  we write  $x(t) = \exp(-\frac{\pi}{N}t^2)$  and define

$$\Theta_q(a, t) = \sum_{n \geq 0} \chi_q(a, n) x(t)^{n^2}.$$

### 7.6.8 Dirichlet L-functions

```
void acb_dirichlet_root_number_theta(acb_t res, const dirichlet_group_t G, const dirichlet_char_t chi, slong prec)
void acb_dirichlet_root_number(acb_t res, const dirichlet_group_t G, const dirichlet_char_t chi, slong prec)
```

Sets *res* to the root number  $\epsilon(\chi)$  for a primitive character *chi*, which appears in the functional equation (where  $p$  is the parity of  $\chi$ ):

$$\left(\frac{q}{\pi}\right)^{\frac{s+p}{2}} \Gamma\left(\frac{s+p}{2}\right) L(s, \chi) = \epsilon(\chi) \left(\frac{q}{\pi}\right)^{\frac{1-s+p}{2}} \Gamma\left(\frac{1-s+p}{2}\right) L(1-s, \bar{\chi})$$

- The *theta* variant uses the evaluation at  $t = 1$  of the Theta series.
- The default version computes it via the gauss sum.

```
void acb_dirichlet_l_hurwitz(acb_t res, const acb_t s, const acb_dirichlet_hurwitz_precomp_t precomp, const dirichlet_group_t G, const dirichlet_char_t chi, slong prec)
```

Computes  $L(s, \chi)$  using decomposition in terms of the Hurwitz zeta function

$$L(s, \chi) = q^{-s} \sum_{k=1}^q \chi(k) \zeta\left(s, \frac{k}{q}\right).$$

If  $s = 1$  and  $\chi$  is non-principal, the deflated Hurwitz zeta function is used to avoid poles.

If *precomp* is *NULL*, each Hurwitz zeta function value is computed directly. If a pre-initialized *precomp* object is provided, this will be used instead to evaluate the Hurwitz zeta function.

```
void acb_dirichlet_l_euler_product(acb_t res, const acb_t s, const dirichlet_group_t G,
                                const dirichlet_char_t chi, slong prec)
```

```
void _acb_dirichlet_euler_product_real_ui(arb_t res, ulong s, const signed char * chi,
                                         int mod, int reciprocal, slong prec)
```

Computes  $L(s, \chi)$  directly using the Euler product. This is efficient if  $s$  has large positive real part. As implemented, this function only gives a finite result if  $\text{re}(s) \geq 2$ .

An error bound is computed via *mag\_hurwitz\_zeta\_uiui()*. If  $s$  is complex, replace it with its real part. Since

$$\frac{1}{L(s, \chi)} = \prod_p \left(1 - \frac{\chi(p)}{p^s}\right) = \sum_{k=1}^{\infty} \frac{\mu(k)\chi(k)}{k^s}$$

and the truncated product gives all smooth-index terms in the series, we have

$$\left| \prod_{p < N} \left(1 - \frac{\chi(p)}{p^s}\right) - \frac{1}{L(s, \chi)} \right| \leq \sum_{k=N}^{\infty} \frac{1}{k^s} = \zeta(s, N).$$

The underscore version specialized for integer  $s$  assumes that  $\chi$  is a real Dirichlet character given by the explicit list *chi* of character values at  $0, 1, \dots, \text{mod} - 1$ . If *reciprocal* is set, it computes  $1/L(s, \chi)$  (this is faster if the reciprocal can be used directly).

```
void acb_dirichlet_l(acb_t res, const acb_t s, const dirichlet_group_t G, const dirich-
                    let_char_t chi, slong prec)
```

Computes  $L(s, \chi)$  using a default choice of algorithm.

```
void acb_dirichlet_l_jet(acb_ptr res, const acb_t s, const dirichlet_group_t G, const dirich-
                        let_char_t chi, int deflate, slong len, slong prec)
```

Computes the Taylor expansion of  $L(s, \chi)$  to length *len*, i.e.  $L(s), L'(s), \dots, L^{(\text{len}-1)}(s)/(\text{len}-1)!$ . If *deflate* is set, computes the expansion of

$$L(s, \chi) - \frac{\sum_{k=1}^q \chi(k)}{(s-1)^q}$$

instead. If *chi* is a principal character, then this has the effect of subtracting the pole with residue  $\sum_{k=1}^q \chi(k) = \phi(q)/q$  that is located at  $s = 1$ . In particular, when evaluated at  $s = 1$ , this gives the regular part of the Laurent expansion. When *chi* is non-principal, *deflate* has no effect.

```
void _acb_dirichlet_l_series(acb_ptr res, acb_srcptr s, slong slen, const dirichlet_group_t G,
                           const dirichlet_char_t chi, int deflate, slong len, slong prec)
```

```
void acb_dirichlet_l_series(acb_poly_t res, const acb_poly_t s, const dirichlet_group_t G,
                           const dirichlet_char_t chi, int deflate, slong len, slong prec)
```

Sets *res* to the power series  $L(s, \chi)$  where  $s$  is a given power series, truncating the result to length *len*. See *acb\_dirichlet\_l\_jet()* for the meaning of the *deflate* flag.

## 7.6.9 Hardy Z-functions

For convenience, setting both *G* and *chi* to *NULL* in the following methods selects the Riemann zeta function.

Currently, these methods require *chi* to be a primitive character.

```
void acb_dirichlet_hardy_theta(acb_ptr res, const acb_t t, const dirichlet_group_t G, const
                             dirichlet_char_t chi, slong len, slong prec)
```

Computes the phase function used to construct the Z-function. We have

$$\theta(t) = -\frac{t}{2} \log(\pi/q) - \frac{i \log(\epsilon)}{2} + \frac{\log \Gamma((s+\delta)/2) - \log \Gamma((1-s+\delta)/2)}{2i}$$

where  $s = 1/2 + it$ ,  $\delta$  is the parity of  $chi$ , and  $\epsilon$  is the root number as computed by `acb_dirichlet_root_number()`. The first  $len$  terms in the Taylor expansion are written to the output.

```
void acb_dirichlet_hardy_z(acb_t res, const acb_t t, const dirichlet_group_t G, const dirichlet_char_t chi,
    long len, long prec)
```

Computes the Hardy Z-function, also known as the Riemann-Siegel Z-function  $Z(t) = e^{i\theta(t)}L(1/2 + it)$ , which is real-valued for real  $t$ . The first  $len$  terms in the Taylor expansion are written to the output.

```
void _acb_dirichlet_hardy_theta_series(acb_ptr res, acb_srcptr t, long tlen, const dirichlet_group_t G,
    const dirichlet_char_t chi, long len, long prec)
```

```
void acb_dirichlet_hardy_theta_series(acb_poly_t res, const acb_poly_t t, const dirichlet_group_t G,
    const dirichlet_char_t chi, long len, long prec)
```

Sets  $res$  to the power series  $\theta(t)$  where  $t$  is a given power series, truncating the result to length  $len$ .

```
void _acb_dirichlet_hardy_z_series(acb_ptr res, acb_srcptr t, long tlen, const dirichlet_group_t G,
    const dirichlet_char_t chi, long len, long prec)
```

```
void acb_dirichlet_hardy_z_series(acb_poly_t res, const acb_poly_t t, const dirichlet_group_t G,
    const dirichlet_char_t chi, long len, long prec)
```

Sets  $res$  to the power series  $Z(t)$  where  $t$  is a given power series, truncating the result to length  $len$ .

## 7.7 bernoulli.h – support for Bernoulli numbers

This module provides helper functions for exact or approximate calculation of the Bernoulli numbers, which are defined by the exponential generating function

$$\frac{x}{e^x - 1} = \sum_{n=0}^{\infty} B_n \frac{x^n}{n!}.$$

Efficient algorithms are implemented for both multi-evaluation and calculation of isolated Bernoulli numbers. A global (or thread-local) cache is also provided, to support fast repeated evaluation of various special functions that depend on the Bernoulli numbers (including the gamma function and the Riemann zeta function).

### 7.7.1 Generation of Bernoulli numbers

#### bernoulli\_rev\_t

An iterator object for generating a range of even-indexed Bernoulli numbers exactly in reverse order, i.e. computing the exact fractions  $B_n, B_{n-2}, B_{n-4}, \dots, B_0$ . The Bernoulli numbers are generated from scratch, i.e. no caching is performed.

The Bernoulli numbers are computed by direct summation of the zeta series. This is made fast by storing a table of powers (as done by [Blo2009]). As an optimization, we only include the odd powers, and use fixed-point arithmetic.

The reverse iteration order is preferred for performance reasons, as the powers can be updated using multiplications instead of divisions, and we avoid having to periodically recompute terms to higher precision. To generate Bernoulli numbers in the forward direction without having to store all of them, one can split the desired range into smaller blocks and compute each block with a single reverse pass.

void **bernoulli\_rev\_init**(*bernoulli\_rev\_t iter*, *ulong n*)  
 Initializes the iterator *iter*. The first Bernoulli number to be generated by calling *bernoulli\_rev\_next()* is  $B_n$ . It is assumed that  $n$  is even.

void **bernoulli\_rev\_next**(*fmpz\_t numer*, *fmpz\_t denom*, *bernoulli\_rev\_t iter*)  
 Sets *numer* and *denom* to the exact, reduced numerator and denominator of the Bernoulli number  $B_k$  and advances the state of *iter* so that the next invocation generates  $B_{k-2}$ .

void **bernoulli\_rev\_clear**(*bernoulli\_rev\_t iter*)  
 Frees all memory allocated internally by *iter*.

## 7.7.2 Caching

*slong* **bernoulli\_cache\_num**

*fmpz* \* **bernoulli\_cache**  
 Cache of Bernoulli numbers. Uses thread-local storage if enabled in FLINT.

void **bernoulli\_cache\_compute**(*slong n*)  
 Makes sure that the Bernoulli numbers up to at least  $B_{n-1}$  are cached. Calling *flint\_cleanup()* frees the cache.

## 7.7.3 Bounding

*slong* **bernoulli\_bound\_2exp\_si**(*ulong n*)  
 Returns an integer  $b$  such that  $|B_n| \leq 2^b$ . Uses a lookup table for small  $n$ , and for larger  $n$  uses the inequality  $|B_n| < 4n!/(2\pi)^n < 4(n+1)^{n+1}e^{-n}/(2\pi)^n$ . Uses integer arithmetic throughout, with the bound for the logarithm being looked up from a table. If  $|B_n| = 0$ , returns *LONG\_MIN*. Otherwise, the returned exponent  $b$  is never more than one percent larger than the true magnitude.

This function is intended for use when  $n$  small enough that one might comfortably compute  $B_n$  exactly. It aborts if  $n$  is so large that internal overflow occurs.

void **\_bernoulli\_fmpz\_ui\_zeta**(*fmpz\_t num*, *fmpz\_t den*, *ulong n*)  
 Sets *num* and *den* to the reduced numerator and denominator of the Bernoulli number  $B_n$ .

This function computes the denominator  $d$  using von Staudt-Clausen theorem, numerically approximates  $B_n$  using *arb\_bernoulli\_ui\_zeta()*, and then rounds  $dB_n$  to the correct numerator. If the working precision is insufficient to determine the numerator, the function prints a warning message and retries with increased precision (this should not be expected to happen).

void **\_bernoulli\_fmpz\_ui**(*fmpz\_t num*, *fmpz\_t den*, *ulong n*)

void **bernoulli\_fmpz\_ui**(*fmpz\_t b*, *ulong n*)  
 Computes the Bernoulli number  $B_n$  as an exact fraction, for an isolated integer  $n$ . This function reads  $B_n$  from the global cache if the number is already cached, but does not automatically extend the cache by itself.

## 7.8 hypgeom.h – support for hypergeometric series

This module provides functions for high-precision evaluation of series of the form

$$\sum_{k=0}^{n-1} \frac{A(k)}{B(k)} \prod_{j=1}^k \frac{P(j)}{Q(j)} z^k$$

where  $A, B, P, Q$  are polynomials. The present version only supports  $A, B, P, Q \in \mathbb{Z}[k]$  (represented using the FLINT *fmpz\_poly\_t* type). This module also provides functions for high-precision evaluation of infinite series ( $n \rightarrow \infty$ ), with automatic, rigorous error bounding.

Note that we can standardize to  $A = B = 1$  by setting  $\tilde{P}(k) = P(k)A(k)B(k-1)$ ,  $\tilde{Q}(k) = Q(k)A(k-1)B(k)$ . However, separating out  $A$  and  $B$  is convenient and improves efficiency during evaluation.

### 7.8.1 Strategy for error bounding

We wish to evaluate  $S(z) = \sum_{k=0}^{\infty} T(k)z^k$  where  $T(k)$  satisfies  $T(0) = 1$  and

$$T(k) = R(k)T(k-1) = \left(\frac{P(k)}{Q(k)}\right) T(k-1)$$

for given polynomials

$$\begin{aligned} P(k) &= a_p k^p + a_{p-1} k^{p-1} + \dots a_0 \\ Q(k) &= b_q k^q + b_{q-1} k^{q-1} + \dots b_0. \end{aligned}$$

For convergence, we require  $p < q$ , or  $p = q$  with  $|z||a_p| < |b_q|$ . We also assume that  $P(k)$  and  $Q(k)$  have no roots among the positive integers (if there are positive integer roots, the sum is either finite or undefined). With these conditions satisfied, our goal is to find a parameter  $n \geq 0$  such that

$$\left| \sum_{k=n}^{\infty} T(k)z^k \right| \leq 2^{-d}.$$

We can rewrite the hypergeometric term ratio as

$$zR(k) = z \frac{P(k)}{Q(k)} = z \left(\frac{a_p}{b_q}\right) \frac{1}{k^{q-p}} F(k)$$

where

$$F(k) = \frac{1 + \tilde{a}_1/k + \tilde{a}_2/k^2 + \dots + \tilde{a}_q/k^p}{1 + \tilde{b}_1/k + \tilde{b}_2/k^2 + \dots + \tilde{b}_q/k^q} = 1 + O(1/k)$$

and where  $\tilde{a}_i = a_{p-i}/a_p$ ,  $\tilde{b}_i = b_{q-i}/b_q$ . Next, we define

$$C = \max_{1 \leq i \leq p} |\tilde{a}_i|^{(1/i)}, \quad D = \max_{1 \leq i \leq q} |\tilde{b}_i|^{(1/i)}.$$

Now, if  $k > C$ , the magnitude of the numerator of  $F(k)$  is bounded from above by

$$1 + \sum_{i=1}^p \left(\frac{C}{k}\right)^i \leq 1 + \frac{C}{k-C}$$

and if  $k > 2D$ , the magnitude of the denominator of  $F(k)$  is bounded from below by

$$1 - \sum_{i=1}^q \left(\frac{D}{k}\right)^i \geq 1 + \frac{D}{D-k}.$$

Putting the inequalities together gives the following bound, valid for  $k > K = \max(C, 2D)$ :

$$|F(k)| \leq \frac{k(k-D)}{(k-C)(k-2D)} = \left(1 + \frac{C}{k-C}\right) \left(1 + \frac{D}{k-2D}\right).$$

Let  $r = q - p$  and  $\tilde{z} = |za_p/b_q|$ . Assuming  $k > \max(C, 2D, \tilde{z}^{1/r})$ , we have

$$|zR(k)| \leq G(k) = \frac{\tilde{z}F(k)}{k^r}$$

where  $G(k)$  is monotonically decreasing. Now we just need to find an  $n$  such that  $G(n) < 1$  and for which  $|T(n)|/(1 - G(n)) \leq 2^{-d}$ . This can be done by computing a floating-point guess for  $n$  then trying successively larger values.

This strategy leaves room for some improvement. For example, if  $\tilde{b}_1$  is positive and large, the bound  $B$  becomes very pessimistic (a larger positive  $\tilde{b}_1$  causes faster convergence, not slower convergence).

## 7.8.2 Types, macros and constants

`hypgeom_struct`

`hypgeom_t`

Stores polynomials  $A$ ,  $B$ ,  $P$ ,  $Q$  and precomputed bounds, representing a fixed hypergeometric series.

## 7.8.3 Memory management

`void hypgeom_init(hypgeom_t hyp)`

`void hypgeom_clear(hypgeom_t hyp)`

## 7.8.4 Error bounding

*slong* `hypgeom_estimate_terms(const mag_t z, int r, slong d)`

Computes an approximation of the largest  $n$  such that  $|z|^n/(n!)^r = 2^{-d}$ , giving a first-order estimate of the number of terms needed to approximate the sum of a hypergeometric series of weight  $r \geq 0$  and argument  $z$  to an absolute precision of  $d \geq 0$  bits. If  $r = 0$ , the direct solution of the equation is given by  $n = (\log(1 - z) - d \log 2)/\log z$ . If  $r > 0$ , using  $\log n! \approx n \log n - n$  gives an equation that can be solved in terms of the Lambert  $W$ -function as  $n = (d \log 2)/(r W(t))$  where  $t = (d \log 2)/(e r z^{1/r})$ .

The evaluation is done using double precision arithmetic. The function aborts if the computed value of  $n$  is greater than or equal to `LONG_MAX / 2`.

*slong* `hypgeom_bound(mag_t error, int r, slong C, slong D, slong K, const mag_t TK, const mag_t z, slong prec)`

Computes a truncation parameter sufficient to achieve  $prec$  bits of absolute accuracy, according to the strategy described above. The input consists of  $r$ ,  $C$ ,  $D$ ,  $K$ , precomputed bound for  $T(K)$ , and  $\tilde{z} = z(a_p/b_q)$ , such that for  $k > K$ , the hypergeometric term ratio is bounded by

$$\frac{\tilde{z}}{k^r} \frac{k(k-D)}{(k-C)(k-2D)}.$$

Given this information, we compute a  $\varepsilon$  and an integer  $n$  such that  $|\sum_{k=n}^{\infty} T(k)| \leq \varepsilon \leq 2^{-prec}$ . The output variable `error` is set to the value of  $\varepsilon$ , and  $n$  is returned.

`void hypgeom_precompute(hypgeom_t hyp)`

Precomputes the bounds data  $C$ ,  $D$ ,  $K$  and an upper bound for  $T(K)$ .

## 7.8.5 Summation

`void arb_hypgeom_sum(arb_t P, arb_t Q, const hypgeom_t hyp, const slong n, slong prec)`

Computes  $P, Q$  such that  $P/Q = \sum_{k=0}^{n-1} T(k)$  where  $T(k)$  is defined by `hyp`, using binary splitting and a working precision of  $prec$  bits.

`void arb_hypgeom_infsum(arb_t P, arb_t Q, hypgeom_t hyp, slong tol, slong prec)`

Computes  $P, Q$  such that  $P/Q = \sum_{k=0}^{\infty} T(k)$  where  $T(k)$  is defined by `hyp`, using binary splitting and working precision of  $prec$  bits. The number of terms is chosen automatically to bound the truncation error by at most  $2^{-tol}$ . The bound for the truncation error is included in the output as part of  $P$ .

## 7.9 partitions.h – computation of the partition function

This module implements the asymptotically fast algorithm for evaluating the integer partition function  $p(n)$  described in [Joh2012]. The idea is to evaluate a truncation of the Hardy-Ramanujan-Rademacher series using tight precision estimates, and symbolically factoring the occurring exponential sums.

An implementation based on floating-point arithmetic can also be found in FLINT. That version relies on some numerical subroutines that have not been proved correct.

The implementation provided here uses ball arithmetic throughout to guarantee a correct error bound for the numerical approximation of  $p(n)$ . Optionally, hardware double arithmetic can be used for low-precision terms. This gives a significant speedup for small (e.g.  $n < 10^6$ ).

void **partitions\_rademacher\_bound**(*arf\_t*  $b$ , const *fmpz\_t*  $n$ , *ulong*  $N$ )

Sets  $b$  to an upper bound for

$$M(n, N) = \frac{44\pi^2}{225\sqrt{3}}N^{-1/2} + \frac{\pi\sqrt{2}}{75} \left(\frac{N}{n-1}\right)^{1/2} \sinh\left(\frac{\pi}{N}\sqrt{\frac{2n}{3}}\right).$$

This formula gives an upper bound for the truncation error in the Hardy-Ramanujan-Rademacher formula when the series is taken up to the term  $t(n, N)$  inclusive.

**partitions\_hrr\_sum\_arb**(*arf\_t*  $x$ , const *fmpz\_t*  $n$ , *slong*  $N0$ , *slong*  $N$ , int *use\_doubles*)

Evaluates the partial sum  $\sum_{k=N0}^N t(n, k)$  of the Hardy-Ramanujan-Rademacher series.

If *use\_doubles* is nonzero, doubles and the system's standard library math functions are used to evaluate the smallest terms. This significantly speeds up evaluation for small  $n$  (e.g.  $n < 10^6$ ), and gives a small speed improvement for larger  $n$ , but the result is not guaranteed to be correct. In practice, the error is estimated very conservatively, and unless the system's standard library is broken, use of doubles can be considered safe. Setting *use\_doubles* to zero gives a fully guaranteed bound.

void **partitions\_fmpz\_fmpz**(*fmpz\_t*  $p$ , const *fmpz\_t*  $n$ , int *use\_doubles*)

Computes the partition function  $p(n)$  using the Hardy-Ramanujan-Rademacher formula. This function computes a numerical ball containing  $p(n)$  and verifies that the ball contains a unique integer.

If  $n$  is sufficiently large and a number of threads greater than 1 has been selected with `flint_set_num_threads()`, the computation time will be reduced by using two threads.

See `partitions_hrr_sum_arb()` for an explanation of the *use\_doubles* option.

void **partitions\_fmpz\_ui**(*fmpz\_t*  $p$ , *ulong*  $n$ )

Computes the partition function  $p(n)$  using the Hardy-Ramanujan-Rademacher formula. This function computes a numerical ball containing  $p(n)$  and verifies that the ball contains a unique integer.

void **partitions\_fmpz\_ui\_using\_doubles**(*fmpz\_t*  $p$ , *ulong*  $n$ )

Computes the partition function  $p(n)$ , enabling the use of doubles internally. This significantly speeds up evaluation for small  $n$  (e.g.  $n < 10^6$ ), but the error bounds are not certified (see remarks for `partitions_hrr_sum_arb()`).

void **partitions\_leading\_fmpz**(*arf\_t*  $res$ , const *fmpz\_t*  $n$ , *slong*  $prec$ )

Sets  $res$  to the leading term in the Hardy-Ramanujan series for  $p(n)$  (without Rademacher's correction of this term, which is vanishingly small when  $n$  is large), that is,  $\sqrt{12}(1 - 1/t)e^t/(24n - 1)$  where  $t = \pi\sqrt{24n - 1}/6$ .

## CALCULUS

Using ball arithmetic, it is possible to do rigorous root-finding and integration (among other operations) with generic functions. This code should be considered experimental.

### 8.1 `arb_calc.h` – calculus with real-valued functions

This module provides functions for operations of calculus over the real numbers (intended to include root-finding, optimization, integration, and so on). It is planned that the module will include two types of algorithms:

- Interval algorithms that give provably correct results. An example would be numerical integration on an interval by dividing the interval into small balls and evaluating the function on each ball, giving rigorous upper and lower bounds.
- Conventional numerical algorithms that use heuristics to estimate the accuracy of a result, without guaranteeing that it is correct. An example would be numerical integration based on pointwise evaluation, where the error is estimated by comparing the results with two different sets of evaluation points. Ball arithmetic then still tracks the accuracy of the function evaluations.

Any algorithms of the second kind will be clearly marked as such.

#### 8.1.1 Types, macros and constants

##### `arb_calc_func_t`

Typedef for a pointer to a function with signature:

```
int func(arb_ptr out, const arb_t inp, void * param, slong order, slong prec)
```

implementing a univariate real function  $f(x)$ . When called, *func* should write to *out* the first *order* coefficients in the Taylor series expansion of  $f(x)$  at the point *inp*, evaluated at a precision of *prec* bits. The *param* argument may be used to pass through additional parameters to the function. The return value is reserved for future use as an error code. It can be assumed that *out* and *inp* are not aliased and that *order* is positive.

##### `ARB_CALC_SUCCESS`

Return value indicating that an operation is successful.

##### `ARB_CALC_IMPRECISE_INPUT`

Return value indicating that the input to a function probably needs to be computed more accurately.

##### `ARB_CALC_NO_CONVERGENCE`

Return value indicating that an algorithm has failed to convergence, possibly due to the problem not having a solution, the algorithm not being applicable, or the precision being insufficient

### 8.1.2 Debugging

int **arb\_calc\_verbose**

If set, enables printing information about the calculation to standard output.

### 8.1.3 Subdivision-based root finding

**arf\_interval\_struct**

**arf\_interval\_t**

An *arf\_interval\_struct* consists of a pair of *arf\_struct*, representing an interval used for subdivision-based root-finding. An *arf\_interval\_t* is defined as an array of length one of type *arf\_interval\_struct*, permitting an *arf\_interval\_t* to be passed by reference.

**arf\_interval\_ptr**

Alias for *arf\_interval\_struct \**, used for vectors of intervals.

**arf\_interval\_srcptr**

Alias for *const arf\_interval\_struct \**, used for vectors of intervals.

void **arf\_interval\_init**(*arf\_interval\_t v*)

void **arf\_interval\_clear**(*arf\_interval\_t v*)

*arf\_interval\_ptr* **\_arf\_interval\_vec\_init**(*slong n*)

void **\_arf\_interval\_vec\_clear**(*arf\_interval\_ptr v, slong n*)

void **arf\_interval\_set**(*arf\_interval\_t v, const arf\_interval\_t u*)

void **arf\_interval\_swap**(*arf\_interval\_t v, arf\_interval\_t u*)

void **arf\_interval\_get\_arb**(*arb\_t x, const arf\_interval\_t v, slong prec*)

void **arf\_interval\_printd**(*const arf\_interval\_t v, slong n*)

Helper functions for endpoint-based intervals.

void **arf\_interval\_fprintfd**(*FILE \* file, const arf\_interval\_t v, slong n*)

Helper functions for endpoint-based intervals.

*slong* **arb\_calc\_isolate\_roots**(*arf\_interval\_ptr \* found, int \*\* flags, arb\_calc\_func\_t func, void \* param, const arf\_interval\_t interval, slong maxdepth, slong maxeval, slong maxfound, slong prec*)

Rigorously isolates single roots of a real analytic function on the interior of an interval.

This routine writes an array of *n* interesting subintervals of *interval* to *found* and corresponding flags to *flags*, returning the integer *n*. The output has the following properties:

- The function has no roots on *interval* outside of the output subintervals.
- Subintervals are sorted in increasing order (with no overlap except possibly starting and ending with the same point).
- Subintervals with a flag of 1 contain exactly one (single) root.
- Subintervals with any other flag may or may not contain roots.

If no flags other than 1 occur, all roots of the function on *interval* have been isolated. If there are output subintervals on which the existence or nonexistence of roots could not be determined, the user may attempt further searches on those subintervals (possibly with increased precision and/or increased bounds for the breaking criteria). Note that roots of multiplicity higher than one and roots located exactly at endpoints cannot be isolated by the algorithm.

The following breaking criteria are implemented:

- At most *maxdepth* recursive subdivisions are attempted. The smallest details that can be distinguished are therefore about  $2^{-\text{maxdepth}}$  times the width of *interval*. A typical, reasonable value might be between 20 and 50.

- If the total number of tested subintervals exceeds *maxeval*, the algorithm is terminated and any untested subintervals are added to the output. The total number of calls to *func* is thereby restricted to a small multiple of *maxeval* (the actual count can be slightly higher depending on implementation details). A typical, reasonable value might be between 100 and 100000.
- The algorithm terminates if *maxfound* roots have been isolated. In particular, setting *maxfound* to 1 can be used to locate just one root of the function even if there are numerous roots. To try to find all roots, *LONG\_MAX* may be passed.

The argument *prec* denotes the precision used to evaluate the function. It is possibly also used for some other arithmetic operations performed internally by the algorithm. Note that it probably does not make sense for *maxdepth* to exceed *prec*.

Warning: it is assumed that subdivision points of *interval* can be represented exactly as floating-point numbers in memory. Do not pass  $1 \pm 2^{-10^{100}}$  as input.

```
int arb_calc_refine_root_bisect(arf_interval_t r, arb_calc_func_t func, void * param, const
                               arf_interval_t start, slong iter, slong prec)
```

Given an interval *start* known to contain a single root of *func*, refines it using *iter* bisection steps. The algorithm can return a failure code if the sign of the function at an evaluation point is ambiguous. The output *r* is set to a valid isolating interval (possibly just *start*) even if the algorithm fails.

#### 8.1.4 Newton-based root finding

```
void arb_calc_newton_conv_factor(arf_t conv_factor, arb_calc_func_t func, void * param,
                                const arb_t conv_region, slong prec)
```

Given an interval *I* specified by *conv\_region*, evaluates a bound for  $C = \sup_{t,u \in I} \frac{1}{2} |f''(t)|/|f'(u)|$ , where *f* is the function specified by *func* and *param*. The bound is obtained by evaluating  $f'(I)$  and  $f''(I)$  directly. If *f* is ill-conditioned, *I* may need to be extremely precise in order to get an effective, finite bound for *C*.

```
int arb_calc_newton_step(arb_t xnew, arb_calc_func_t func, void * param, const arb_t x, const
                        arb_t conv_region, const arf_t conv_factor, slong prec)
```

Performs a single step with an interval version of Newton's method. The input consists of the function *f* specified by *func* and *param*, a ball  $x = [m - r, m + r]$  known to contain a single root of *f*, a ball *I* (*conv\_region*) containing *x* with an associated bound (*conv\_factor*) for  $C = \sup_{t,u \in I} \frac{1}{2} |f''(t)|/|f'(u)|$ , and a working precision *prec*.

The Newton update consists of setting  $x' = [m' - r', m' + r']$  where  $m' = m - f(m)/f'(m)$  and  $r' = Cr^2$ . The expression  $m - f(m)/f'(m)$  is evaluated using ball arithmetic at a working precision of *prec* bits, and the rounding error during this evaluation is accounted for in the output. We now check that  $x' \in I$  and  $r' < r$ . If both conditions are satisfied, we set *xnew* to  $x'$  and return *ARB\_CALC\_SUCCESS*. If either condition fails, we set *xnew* to *x* and return *ARB\_CALC\_NO\_CONVERGENCE*, indicating that no progress is made.

```
int arb_calc_refine_root_newton(arb_t r, arb_calc_func_t func, void * param,
                                const arb_t start, const arb_t conv_region, const
                                arf_t conv_factor, slong eval_extra_prec, slong prec)
```

Refines a precise estimate of a single root of a function to high precision by performing several Newton steps, using nearly optimally chosen doubling precision steps.

The inputs are defined as for *arb\_calc\_newton\_step*, except for the precision parameters: *prec* is the target accuracy and *eval\_extra\_prec* is the estimated number of guard bits that need to be added to evaluate the function accurately close to the root (for example, if the function is a polynomial with large coefficients of alternating signs and Horner's rule is used to evaluate it, the extra precision should typically be approximately the bit size of the coefficients).

This function returns *ARB\_CALC\_SUCCESS* if all attempted Newton steps are successful (note that this does not guarantee that the computed root is accurate to *prec* bits, which has to be verified by the user), only that it is more accurate than the starting ball.

On failure, `ARB_CALC_IMPRECISE_INPUT` or `ARB_CALC_NO_CONVERGENCE` may be returned. In this case,  $r$  is set to a ball for the root which is valid but likely does not have full accuracy (it can possibly just be equal to the starting ball).

## 8.2 `acb_calc.h` – calculus with complex-valued functions

This module provides functions for operations of calculus over the complex numbers (intended to include root-finding, integration, and so on).

### 8.2.1 Types, macros and constants

`acb_calc_func_t`

Typedef for a pointer to a function with signature:

```
int func(acb_ptr out, const acb_t inp, void * param, slong order, slong prec)
```

implementing a univariate complex function  $f(x)$ . When called, `func` should write to `out` the first `order` coefficients in the Taylor series expansion of  $f(x)$  at the point `inp`, evaluated at a precision of `prec` bits. The `param` argument may be used to pass through additional parameters to the function. The return value is reserved for future use as an error code. It can be assumed that `out` and `inp` are not aliased and that `order` is positive.

### 8.2.2 Bounds

void `acb_calc_cauchy_bound`(`arb_t bound`, `acb_calc_func_t func`, void \* `param`, const `acb_t x`, const `arb_t radius`, `slong maxdepth`, `slong prec`)

Sets `bound` to a ball containing the value of the integral

$$C(x, r) = \frac{1}{2\pi r} \oint_{|z-x|=r} |f(z)| dz = \int_0^1 |f(x + re^{2\pi it})| dt$$

where  $f$  is specified by  $(func, param)$  and  $r$  is given by `radius`. The integral is computed using a simple step sum. The integration range is subdivided until the order of magnitude of  $b$  can be determined (i.e. its error bound is smaller than its midpoint), or until the step length has been cut in half `maxdepth` times. This function is currently implemented completely naively, and repeatedly subdivides the whole integration range instead of performing adaptive subdivisions.

### 8.2.3 Integration

int `acb_calc_integrate_taylor`(`acb_t res`, `acb_calc_func_t func`, void \* `param`, const `acb_t a`, const `acb_t b`, const `arf_t inner_radius`, const `arf_t outer_radius`, `slong accuracy_goal`, `slong prec`)

Computes the integral

$$I = \int_a^b f(t) dt$$

where  $f$  is specified by  $(func, param)$ , following a straight-line path between the complex numbers  $a$  and  $b$  which both must be finite.

The integral is approximated by piecewise centered Taylor polynomials. Rigorous truncation error bounds are calculated using the Cauchy integral formula. More precisely, if the Taylor series of  $f$  centered at the point  $m$  is  $f(m+x) = \sum_{n=0}^{\infty} a_n x^n$ , then

$$\int f(m+x) = \left( \sum_{n=0}^{N-1} a_n \frac{x^{n+1}}{n+1} \right) + \left( \sum_{n=N}^{\infty} a_n \frac{x^{n+1}}{n+1} \right).$$

For sufficiently small  $x$ , the second series converges and its absolute value is bounded by

$$\sum_{n=N}^{\infty} \frac{C(m, R)}{R^n} \frac{|x|^{n+1}}{N+1} = \frac{C(m, R)Rx}{(R-x)(N+1)} \left(\frac{x}{R}\right)^N.$$

It is required that any singularities of  $f$  are isolated from the path of integration by a distance strictly greater than the positive value *outer\_radius* (which is the integration radius used for the Cauchy bound). Taylor series step lengths are chosen so as not to exceed *inner\_radius*, which must be strictly smaller than *outer\_radius* for convergence. A smaller *inner\_radius* gives more rapid convergence of each Taylor series but means that more series might have to be used. A reasonable choice might be to set *inner\_radius* to half the value of *outer\_radius*, giving roughly one accurate bit per term.

The truncation point of each Taylor series is chosen so that the absolute truncation error is roughly  $2^{-p}$  where  $p$  is given by *accuracy\_goal* (in the future, this might change to a relative accuracy). Arithmetic operations and function evaluations are performed at a precision of *prec* bits. Note that due to accumulation of numerical errors, both values may have to be set higher (and the endpoints may have to be computed more accurately) to achieve a desired accuracy.

This function chooses the evaluation points uniformly rather than implementing adaptive subdivision.

## EXTRA UTILITY MODULES

Mainly for internal use.

### 9.1 `fmpz_extras.h` – extra methods for FLINT integers

This module implements a few utility methods for the FLINT multiprecision integer type (`fmpz_t`). It is mainly intended for internal use.

#### 9.1.1 Memory-related methods

*slong* `fmpz_allocated_bytes(const fmpz_t x)`

Returns the total number of bytes heap-allocated internally by this object. The count excludes the size of the structure itself. Add `sizeof(fmpz)` to get the size of the object as a whole.

#### 9.1.2 Convenience methods

void `fmpz_add_si(fmpz_t z, const fmpz_t x, slong y)`

void `fmpz_sub_si(fmpz_t z, const fmpz_t x, slong y)`  
Sets  $z$  to the sum (respectively difference) of  $x$  and  $y$ .

void `fmpz_adiv_q_2exp(fmpz_t z, const fmpz_t x, mp_bitcnt_t exp)`  
Sets  $z$  to  $x/2^{exp}$ , rounded away from zero.

void `fmpz_ui_pow_ui(fmpz_t x, ulong b, ulong e)`  
Sets  $x$  to  $b$  raised to the power  $e$ .

void `fmpz_max(fmpz_t z, const fmpz_t x, const fmpz_t y)`

void `fmpz_min(fmpz_t z, const fmpz_t x, const fmpz_t y)`  
Sets  $z$  to the maximum (respectively minimum) of  $x$  and  $y$ .

#### 9.1.3 Inlined arithmetic

The `fmpz_t` bignum type uses an immediate representation for small integers, specifically when the absolute value is at most  $2^{62} - 1$  (on 64-bit machines) or  $2^{30} - 1$  (on 32-bit machines). The following methods completely inline the case where all operands (and possibly some intermediate values in the calculation) are known to be small. This is faster in code where all values *almost certainly will be much smaller than a full word*. In particular, these methods are used within Arb for manipulating exponents of floating-point numbers. Inlining slows down the general case, and increases code size, so these methods should not be used gratuitously.

void `fmpz_add_inline(fmpz_t z, const fmpz_t x, const fmpz_t y)`

void `fmpz_add_si_inline(fmpz_t z, const fmpz_t x, slong y)`

void **fmpz\_add\_ui\_inline**(*fmpz\_t* z, const *fmpz\_t* x, *ulong* y)  
Sets *z* to the sum of *x* and *y*.

void **fmpz\_sub\_si\_inline**(*fmpz\_t* z, const *fmpz\_t* x, *slong* y)  
Sets *z* to the difference of *x* and *y*.

void **fmpz\_add2\_fmpz\_si\_inline**(*fmpz\_t* z, const *fmpz\_t* x, const *fmpz\_t* y, *slong* c)  
Sets *z* to the sum of *x*, *y*, and *c*.

*mp\_size\_t* **fmpz\_size**(const *fmpz\_t* x)  
Returns the number of limbs required to represent *x*.

*slong* **fmpz\_sub\_small**(const *fmpz\_t* x, const *fmpz\_t* y)  
Computes the difference of *x* and *y* and returns the result as an *slong*. The result is clamped between  $-WORD\_MAX$  and  $WORD\_MAX$ , i.e. between  $\pm(2^{63}-1)$  inclusive on a 64-bit machine.

### 9.1.4 Low-level conversions

void **fmpz\_set\_mpn\_large**(*fmpz\_t* z, *mp\_srcptr* src, *mp\_size\_t* n, int *negative*)  
Sets *z* to the integer represented by the *n* limbs in the array *src*, or minus this value if *negative* is 1. Requires  $n \geq 2$  and that the top limb of *src* is nonzero. Note that *fmpz\_set\_ui*, *fmpz\_neg\_ui* can be used for single-limb integers.

void **FMPZ\_GET\_MPN\_READONLY**(zsign, zn, zptr, ztmp, zv)  
Given an *fmpz\_t* *zv*, this macro sets *zptr* to a pointer to the limbs of *zv*, *zn* to the number of limbs, and *zsign* to a sign bit (0 if nonnegative, 1 if negative). The variable *ztmp* must be a single *mp\_limb\_t*, which is used as a buffer. If *zv* is a small value, *zv* itself contains no limb array that *zptr* could point to, so the single limb is copied to *ztmp* and *zptr* is set to point to *ztmp*. The case where *zv* is zero is not handled specially, and *zn* is set to 1.

void **fmpz\_lshift\_mpn**(*fmpz\_t* z, *mp\_srcptr* src, *mp\_size\_t* n, int *negative*, *mp\_bitcnt\_t* shift)  
Sets *z* to the integer represented by the *n* limbs in the array *src*, or minus this value if *negative* is 1, shifted left by *shift* bits. Requires  $n \geq 1$  and that the top limb of *src* is nonzero.

## 9.2 bool\_mat.h – matrices over booleans

A *bool\_mat\_t* represents a dense matrix over the boolean semiring  $\langle\{0,1\}, \vee, \wedge\rangle$ , implemented as an array of entries of type *int*.

The dimension (number of rows and columns) of a matrix is fixed at initialization, and the user must ensure that inputs and outputs to an operation have compatible dimensions. The number of rows or columns in a matrix can be zero.

### 9.2.1 Types, macros and constants

**bool\_mat\_struct**

**bool\_mat\_t**

Contains a pointer to a flat array of the entries (entries), an array of pointers to the start of each row (rows), and the number of rows (r) and columns (c).

An *bool\_mat\_t* is defined as an array of length one of type *bool\_mat\_struct*, permitting an *bool\_mat\_t* to be passed by reference.

int **bool\_mat\_get\_entry**(const *bool\_mat\_t* mat, *slong* i, *slong* j)  
Returns the entry of matrix *mat* at row *i* and column *j*.

void **bool\_mat\_set\_entry**(*bool\_mat\_t* mat, *slong* i, *slong* j, int x)  
Sets the entry of matrix *mat* at row *i* and column *j* to *x*.

**bool\_mat\_nrows**(*mat*)  
Returns the number of rows of the matrix.

**bool\_mat\_ncols**(*mat*)  
Returns the number of columns of the matrix.

## 9.2.2 Memory management

void **bool\_mat\_init**(*bool\_mat\_t mat*, *slong r*, *slong c*)  
Initializes the matrix, setting it to the zero matrix with *r* rows and *c* columns.

void **bool\_mat\_clear**(*bool\_mat\_t mat*)  
Clears the matrix, deallocating all entries.

int **bool\_mat\_is\_empty**(const *bool\_mat\_t mat*)  
Returns nonzero iff the number of rows or the number of columns in *mat* is zero. Note that this does not depend on the entry values of *mat*.

int **bool\_mat\_is\_square**(const *bool\_mat\_t mat*)  
Returns nonzero iff the number of rows is equal to the number of columns in *mat*.

## 9.2.3 Conversions

void **bool\_mat\_set**(*bool\_mat\_t dest*, const *bool\_mat\_t src*)  
Sets *dest* to *src*. The operands must have identical dimensions.

## 9.2.4 Input and output

void **bool\_mat\_print**(const *bool\_mat\_t mat*)  
Prints each entry in the matrix.

void **bool\_mat\_fprint**(FILE \* *file*, const *bool\_mat\_t mat*)  
Prints each entry in the matrix to the stream *file*.

## 9.2.5 Value comparisons

int **bool\_mat\_equal**(const *bool\_mat\_t mat1*, const *bool\_mat\_t mat2*)  
Returns nonzero iff the matrices have the same dimensions and identical entries.

int **bool\_mat\_any**(const *bool\_mat\_t mat*)  
Returns nonzero iff *mat* has a nonzero entry.

int **bool\_mat\_all**(const *bool\_mat\_t mat*)  
Returns nonzero iff all entries of *mat* are nonzero.

int **bool\_mat\_is\_diagonal**(const *bool\_mat\_t A*)  
Returns nonzero iff  $i \neq j \implies \bar{A}_{ij}$ .

int **bool\_mat\_is\_lower\_triangular**(const *bool\_mat\_t A*)  
Returns nonzero iff  $i < j \implies \bar{A}_{ij}$ .

int **bool\_mat\_is\_transitive**(const *bool\_mat\_t mat*)  
Returns nonzero iff  $A_{ij} \wedge A_{jk} \implies A_{ik}$ .

int **bool\_mat\_is\_nilpotent**(const *bool\_mat\_t A*)  
Returns nonzero iff some positive matrix power of *A* is zero.

### 9.2.6 Random generation

void **bool\_mat\_randtest**(*bool\_mat\_t* mat, *flint\_rand\_t* state)  
Sets *mat* to a random matrix.

void **bool\_mat\_randtest\_diagonal**(*bool\_mat\_t* mat, *flint\_rand\_t* state)  
Sets *mat* to a random diagonal matrix.

void **bool\_mat\_randtest\_nilpotent**(*bool\_mat\_t* mat, *flint\_rand\_t* state)  
Sets *mat* to a random nilpotent matrix.

### 9.2.7 Special matrices

void **bool\_mat\_zero**(*bool\_mat\_t* mat)  
Sets all entries in *mat* to zero.

void **bool\_mat\_one**(*bool\_mat\_t* mat)  
Sets the entries on the main diagonal to ones, and all other entries to zero.

void **bool\_mat\_directed\_path**(*bool\_mat\_t* A)  
Sets  $A_{ij}$  to  $j = i + 1$ . Requires that *A* is a square matrix.

void **bool\_mat\_directed\_cycle**(*bool\_mat\_t* A)  
Sets  $A_{ij}$  to  $j = (i + 1) \bmod n$  where *n* is the order of the square matrix *A*.

### 9.2.8 Transpose

void **bool\_mat\_transpose**(*bool\_mat\_t* dest, const *bool\_mat\_t* src)  
Sets *dest* to the transpose of *src*. The operands must have compatible dimensions. Aliasing is allowed.

### 9.2.9 Arithmetic

void **bool\_mat\_complement**(*bool\_mat\_t* B, const *bool\_mat\_t* A)  
Sets *B* to the logical complement of *A*. That is  $B_{ij}$  is set to  $\bar{A}_{ij}$ . The operands must have the same dimensions.

void **bool\_mat\_add**(*bool\_mat\_t* res, const *bool\_mat\_t* mat1, const *bool\_mat\_t* mat2)  
Sets *res* to the sum of *mat1* and *mat2*. The operands must have the same dimensions.

void **bool\_mat\_mul**(*bool\_mat\_t* res, const *bool\_mat\_t* mat1, const *bool\_mat\_t* mat2)  
Sets *res* to the matrix product of *mat1* and *mat2*. The operands must have compatible dimensions for matrix multiplication.

void **bool\_mat\_mul\_entrywise**(*bool\_mat\_t* res, const *bool\_mat\_t* mat1, const *bool\_mat\_t* mat2)  
Sets *res* to the entrywise product of *mat1* and *mat2*. The operands must have the same dimensions.

void **bool\_mat\_sqr**(*bool\_mat\_t* B, const *bool\_mat\_t* A)  
Sets *B* to the matrix square of *A*. The operands must both be square with the same dimensions.

void **bool\_mat\_pow\_ui**(*bool\_mat\_t* B, const *bool\_mat\_t* A, *ulong* exp)  
Sets *B* to *A* raised to the power *exp*. Requires that *A* is a square matrix.

### 9.2.10 Special functions

int **bool\_mat\_trace**(const *bool\_mat\_t* mat)  
Returns the trace of the matrix, i.e. the sum of entries on the main diagonal of *mat*. The matrix is required to be square. The sum is in the boolean semiring, so this function returns nonzero iff any entry on the diagonal of *mat* is nonzero.

*slong* **bool\_mat\_nilpotency\_degree**(const *bool\_mat\_t* A)

Returns the nilpotency degree of the  $n \times n$  matrix  $A$ . It returns the smallest positive  $k$  such that  $A^k = 0$ . If no such  $k$  exists then the function returns  $-1$  if  $n$  is positive, and otherwise it returns  $0$ .

void **bool\_mat\_transitive\_closure**(*bool\_mat\_t* B, const *bool\_mat\_t* A)

Sets  $B$  to the transitive closure  $\sum_{k=1}^{\infty} A^k$ . The matrix  $A$  is required to be square.

*slong* **bool\_mat\_get\_strongly\_connected\_components**(*slong* \* p, const *bool\_mat\_t* A)

Partitions the  $n$  row and column indices of the  $n \times n$  matrix  $A$  according to the strongly connected components (SCC) of the graph for which  $A$  is the adjacency matrix. If the graph has  $k$  SCCs then the function returns  $k$ , and for each vertex  $i \in [0, n - 1]$ ,  $p_i$  is set to the index of the SCC to which the vertex belongs. The SCCs themselves can be considered as nodes in a directed acyclic graph (DAG), and the SCCs are indexed in postorder with respect to that DAG.

*slong* **bool\_mat\_all\_pairs\_longest\_walk**(*fmpz\_mat\_t* B, const *bool\_mat\_t* A)

Sets  $B_{ij}$  to the length of the longest walk with endpoint vertices  $i$  and  $j$  in the graph whose adjacency matrix is  $A$ . The matrix  $A$  must be square. Empty walks with zero length which begin and end at the same vertex are allowed. If  $j$  is not reachable from  $i$  then no walk from  $i$  to  $j$  exists and  $B_{ij}$  is set to the special value  $-1$ . If arbitrarily long walks from  $i$  to  $j$  exist then  $B_{ij}$  is set to the special value  $-2$ .

The function returns  $-2$  if any entry of  $B_{ij}$  is  $-2$ , and otherwise it returns the maximum entry in  $B$ , except if  $A$  is empty in which case  $-1$  is returned. Note that the returned value is one less than that of `nilpotency_degree()`.

This function can help quantify entrywise errors in a truncated evaluation of a matrix power series. If  $A$  is an indicator matrix with the same sparsity pattern as a matrix  $M$  over the real or complex numbers, and if  $B_{ij}$  does not take the special value  $-2$ , then the tail  $[\sum_{k=N}^{\infty} a_k M^k]_{ij}$  vanishes when  $N > B_{ij}$ .

## 9.3 dlog.h – discrete logarithms mod ulong primes

This module implements discrete logarithms, with the application to Dirichlet characters in mind.

In particular, this module defines a *dlog\_precomp\_t* structure permitting to describe a discrete log problem in some subgroup of  $(\mathbb{Z}/p^e\mathbb{Z})^\times$  for primepower moduli  $p^e$ , and store precomputed data for faster computation of several such discrete logarithms.

When initializing this data, the user provides both a group description and the expected number of subsequent discrete logarithms calls. The choice of algorithm and the amount of stored data depend both on the structure of the group and this number.

No particular effort has been made towards single discrete logarithm computation. Currently only machine size primepower moduli are supported.

### 9.3.1 Types, macros and constants

**DLOG\_NONE**

Return value when the discrete logarithm does not exist

**dlog\_precomp\_struct**

**dlog\_precomp\_t**

Structure for discrete logarithm precomputed data.

A *dlog\_precomp\_t* is defined as an array of length one of type *dlog\_precomp\_struct*, permitting a *dlog\_precomp\_t* to be passed by reference.

### 9.3.2 Single evaluation

*ulong* **dlog\_once**(*ulong* *b*, *ulong* *a*, const *nmod\_t* *mod*, *ulong* *n*)

Return  $x$  such that  $b = a^x$  in  $(\mathbb{Z}/\text{mod}\mathbb{Z})^\times$ , where  $a$  is known to have order  $n$ .

### 9.3.3 Precomputations

void **dlog\_precomp\_n\_init**(*dlog\_precomp\_t* *pre*, *ulong* *a*, *ulong* *mod*, *ulong* *n*, *ulong* *num*)

Precompute data for *num* discrete logarithms evaluations in the subgroup generated by *a* modulo *mod*, where *a* is known to have order *n*.

*ulong* **dlog\_precomp**(const *dlog\_precomp\_t* *pre*, *ulong* *b*)

Return  $\log(b)$  for the group described in *pre*.

void **dlog\_precomp\_clear**(*dlog\_precomp\_t* *pre*)

Clears *t*.

Specialized versions of **dlog\_precomp\_n\_init()** are available when specific information is known about the group:

void **dlog\_precomp\_modpe\_init**(*dlog\_precomp\_t* *pre*, *ulong* *a*, *ulong* *p*, *ulong* *e*, *ulong* *pe*, *ulong* *num*)

Assume that *a* generates the group of residues modulo *pe* equal  $p^e$  for prime *p*.

void **dlog\_precomp\_p\_init**(*dlog\_precomp\_t* *pre*, *ulong* *a*, *ulong* *mod*, *ulong* *p*, *ulong* *num*)

Assume that *a* has prime order *p*.

void **dlog\_precomp\_pe\_init**(*dlog\_precomp\_t* *pre*, *ulong* *a*, *ulong* *mod*, *ulong* *p*, *ulong* *e*, *ulong* *pe*, *ulong* *num*)

Assume that *a* has primepower order  $pe$ .

void **dlog\_precomp\_small\_init**(*dlog\_precomp\_t* *pre*, *ulong* *a*, *ulong* *mod*, *ulong* *n*, *ulong* *num*)

Make a complete lookup table of size *n*. If *mod* is small, this is done using an element-indexed array (see **dlog\_table\_t**), otherwise with a sorted array allowing binary search.

### 9.3.4 Vector evaluations

These functions compute all logarithms of successive integers  $1 \dots n$ .

void **dlog\_vec\_fill**(*ulong* \* *v*, *ulong* *nv*, *ulong* *x*)

Sets values  $v[k]$  to *x* for all *k* less than *nv*.

void **dlog\_vec\_set\_not\_found**(*ulong* \* *v*, *ulong* *nv*, *nmod\_t* *mod*)

Sets values  $v[k]$  to **DLOG\_NONE** for all *k* not coprime to *mod*.

void **dlog\_vec**(*ulong* \* *v*, *ulong* *nv*, *ulong* *a*, *ulong* *va*, *nmod\_t* *mod*, *ulong* *na*, *nmod\_t* *order*)

Sets  $v[k]$  to  $\log(k, a)$  times value *va* for  $0 \leq k < nv$ , where *a* has order *na*. *va* should be 1 for usual log computation.

void **dlog\_vec\_add**(*ulong* \* *v*, *ulong* *nv*, *ulong* *a*, *ulong* *va*, *nmod\_t* *mod*, *ulong* *na*, *nmod\_t* *order*)

Same parameters as before, but adds  $\log(k, a) \times v_a$  to  $v[k]$  and reduce modulo *order* instead of replacing the value. Indices *k* such that  $v[k]$  equals **DLOG\_NONE** are ignored.

Depending on the relative size of *nv* and *na*, these two **dlog\_vec** functions call one of the following functions.

void **dlog\_vec\_loop**(*ulong* \* *v*, *ulong* *nv*, *ulong* *a*, *ulong* *va*, *nmod\_t* *mod*, *ulong* *na*, *nmod\_t* *order*)

void **dlog\_vec\_loop\_add**(*ulong* \* *v*, *ulong* *nv*, *ulong* *a*, *ulong* *va*, *nmod\_t* *mod*, *ulong* *na*, *nmod\_t* *order*)

Perform a complete loop of size *na* on powers of *a* to fill the logarithm values, discarding powers outside the bounds of *v*. This requires no discrete logarithm computation.

```
void dlog_vec_eratos(ulong * v, ulong nv, ulong a, ulong va, nmod_t mod, ulong na, nmod_t order)
```

```
void dlog_vec_eratos_add(ulong * v, ulong nv, ulong a, ulong va, nmod_t mod, ulong na, nmod_t order)
```

Compute discrete logarithms of prime numbers less than *nv* and propagate to composite numbers.

```
void dlog_vec_sieve_add(ulong * v, ulong nv, ulong a, ulong va, nmod_t mod, ulong na, nmod_t order)
```

```
void dlog_vec_sieve(ulong * v, ulong nv, ulong a, ulong va, nmod_t mod, ulong na, nmod_t order)
```

Compute the discrete logarithms of the first few prime numbers, then use them as a factor base to obtain the logarithms of larger primes by sieving techniques.

In the the present implementation, the full index-calculus method is not implemented.

### 9.3.5 Internal discrete logarithm strategies

Several discrete logarithms strategies are implemented:

- Complete lookup table for small groups.
- Baby-step giant-step table.

combined with mathematical reductions:

- Pohlig-Hellman decomposition (Chinese remainder decomposition on the order of the group and base *p* decomposition for primepower order).
- p-adic log for primepower modulus  $p^e$ .

The *dlog\_precomp* structure makes recursive use of the following method-specific structures.

#### Complete table

**dlog\_table**

**dlog\_table\_t**

Structure for complete lookup table.

```
ulong dlog_table_init(dlog_table_t t, ulong a, ulong mod)
```

Initialize a table of powers of *a* modulo *mod*, storing all elements in an array of size *mod*.

```
void dlog_table_clear(dlog_table_t t)
```

Clears *t*.

```
ulong dlog_table(dlog_table_t t, ulong b)
```

Return  $\log(b, a)$  using the precomputed data *t*.

#### Baby-step giant-step table

**dlog\_bsgs\_struct**

**dlog\_bsgs\_t**

Structure for Baby-Step Giant-Step decomposition.

```
ulong dlog_bsgs_init(dlog_bsgs_t t, ulong a, ulong mod, ulong n, ulong m)
```

Initialize *t* and store the first *m* powers of *a* in a sorted array. The return value is a rough measure of the cost of each logarithm using this table. The user should take  $m \approx \sqrt{kn}$  to compute *k* logarithms in a group of size *n*.

```
void dlog_bsgs_clear(dlog_bsgs_t t)
```

Clears *t*.

*ulong* **dlog\_bsgs**(*dlog\_bsgs\_t* *t*, *ulong* *b*)  
Return  $\log(b, a)$  using the precomputed data *t*.

### Prime-power modulus decomposition

**dlog\_modpe\_struct**

**dlog\_modpe\_t**

Structure for discrete logarithm modulo primepower  $p^e$ .

A *dlog\_modpe\_t* is defined as an array of length one of type *dlog\_modpe\_struct*, permitting a *dlog\_modpe\_t* to be passed by reference.

*ulong* **dlog\_modpe\_init**(*dlog\_modpe\_t* *t*, *ulong* *a*, *ulong* *p*, *ulong* *e*, *ulong* *pe*, *ulong* *num*)

void **dlog\_modpe\_clear**(*dlog\_modpe\_t* *t*)

Clears *t*.

*ulong* **dlog\_modpe**(*dlog\_modpe\_t* *t*, *ulong* *b*)  
Return  $\log(b, a)$  using the precomputed data *t*.

### CRT decomposition

**dlog\_crt\_struct**

**dlog\_crt\_t**

Structure for discrete logarithm for groups of composite order. A *dlog\_crt\_t* is defined as an array of length one of type *dlog\_crt\_struct*, permitting a *dlog\_crt\_t* to be passed by reference.

*ulong* **dlog\_crt\_init**(*dlog\_crt\_t* *t*, *ulong* *a*, *ulong* *mod*, *ulong* *n*, *ulong* *num*)

Precompute data for *num* evaluations of discrete logarithms in base *a* modulo *mod*, where *a* has composite order *n*, using chinese remainder decomposition.

void **dlog\_crt\_clear**(*dlog\_crt\_t* *t*)

Clears *t*.

*ulong* **dlog\_crt**(*dlog\_crt\_t* *t*, *ulong* *b*)  
Return  $\log(b, a)$  using the precomputed data *t*.

### padic decomposition

**dlog\_power\_struct**

**dlog\_power\_t**

Structure for discrete logarithm for groups of primepower order. A *dlog\_power\_t* is defined as an array of length one of type *dlog\_power\_struct*, permitting a *dlog\_power\_t* to be passed by reference.

*ulong* **dlog\_power\_init**(*dlog\_power\_t* *t*, *ulong* *a*, *ulong* *mod*, *ulong* *p*, *ulong* *e*, *ulong* *num*)

Precompute data for *num* evaluations of discrete logarithms in base *a* modulo *mod*, where *a* has prime power order *pe* equals  $p^e$ , using decomposition in base *p*.

void **dlog\_power\_clear**(*dlog\_power\_t* *t*)

Clears *t*.

*ulong* **dlog\_power**(*dlog\_power\_t* *t*, *ulong* *b*)  
Return  $\log(b, a)$  using the precomputed data *t*.

## Pollard rho method

**dlog\_rho\_struct**

**dlog\_rho\_t**

Structure for discrete logarithm using Pollard rho. A *dlog\_rho\_t* is defined as an array of length one of type *dlog\_rho\_struct*, permitting a *dlog\_rho\_t* to be passed by reference.

*ulong* **dlog\_rho\_init**(*dlog\_rho\_t* t, *ulong* a, *ulong* mod, *ulong* n, *ulong* num)

Initialize random walks for evaluations of discrete logarithms in base *a* modulo *mod*, where *a* has order *n*.

void **dlog\_rho\_clear**(*dlog\_rho\_t* t)

Clears *t*.

*ulong* **dlog\_rho**(*dlog\_rho\_t* t, *ulong* b)

Return  $\log(b, a)$  by the rho method in the group described by *t*.

## 9.4 fmpr.h – Arb 1.x floating-point numbers (deprecated)

This module is deprecated, and any methods contained herein could disappear in the future. This module is mainly kept for testing the faster *arf\_t* type that was introduced in Arb 2.0. Please use *arf\_t* instead of the *fmpr\_t* type.

A variable of type *fmpr\_t* holds an arbitrary-precision binary floating-point number, i.e. a rational number of the form  $x \times 2^y$  where  $x, y \in \mathbb{Z}$  and *x* is odd; or one of the special values zero, plus infinity, minus infinity, or NaN (not-a-number).

The component *x* is called the *mantissa*, and *y* is called the *exponent*. Note that this is just one among many possible conventions: the mantissa (alternatively *significand*) is sometimes viewed as a fraction in the interval  $[1/2, 1)$ , with the exponent pointing to the position above the top bit rather than the position of the bottom bit, and with a separate sign.

The conventions for special values largely follow those of the IEEE floating-point standard. At the moment, there is no support for negative zero, unsigned infinity, or a NaN with a payload, though some these might be added in the future.

An *fmpr* number is exact and has no inherent “accuracy”. We use the term *precision* to denote either the target precision of an operation, or the bit size of a mantissa (which in general is unrelated to the “accuracy” of the number: for example, the floating-point value 1 has a precision of 1 bit in this sense and is simultaneously an infinitely accurate approximation of the integer 1 and a 2-bit accurate approximation of  $\sqrt{2} = 1.011010100\dots_2$ ).

Except where otherwise noted, the output of an operation is the floating-point number obtained by taking the inputs as exact numbers, in principle carrying out the operation exactly, and rounding the resulting real number to the nearest representable floating-point number whose mantissa has at most the specified number of bits, in the specified direction of rounding. Some operations are always or optionally done exactly.

### 9.4.1 Types, macros and constants

**fmpr\_struct**

An *fmpr\_struct* holds a mantissa and an exponent. If the mantissa and exponent are sufficiently small, their values are stored as immediate values in the *fmpr\_struct*; large values are represented by pointers to heap-allocated arbitrary-precision integers. Currently, both the mantissa and exponent are implemented using the FLINT *mpz* type. Special values are currently encoded by the mantissa being set to zero.

**fmpr\_t**

An *fmpr\_t* is defined as an array of length one of type *fmpr\_struct*, permitting an *fmpr\_t* to be passed by reference.

**fmpr\_rnd\_t**

Specifies the rounding mode for the result of an approximate operation.

**FMPR\_RND\_DOWN**

Specifies that the result of an operation should be rounded to the nearest representable number in the direction towards zero.

**FMPR\_RND\_UP**

Specifies that the result of an operation should be rounded to the nearest representable number in the direction away from zero.

**FMPR\_RND\_FLOOR**

Specifies that the result of an operation should be rounded to the nearest representable number in the direction towards minus infinity.

**FMPR\_RND\_CEIL**

Specifies that the result of an operation should be rounded to the nearest representable number in the direction towards plus infinity.

**FMPR\_RND\_NEAR**

Specifies that the result of an operation should be rounded to the nearest representable number, rounding to an odd mantissa if there is a tie between two values. *Warning:* this rounding mode is currently not implemented (except for a few conversions functions where this stated explicitly).

**FMPR\_PREC\_EXACT**

If passed as the precision parameter to a function, indicates that no rounding is to be performed. This must only be used when it is known that the result of the operation can be represented exactly and fits in memory (the typical use case is working small integer values). Note that, for example, adding two numbers whose exponents are far apart can easily produce an exact result that is far too large to store in memory.

## 9.4.2 Memory management

void **fmpr\_init**(*fmpr\_t* *x*)

Initializes the variable *x* for use. Its value is set to zero.

void **fmpr\_clear**(*fmpr\_t* *x*)

Clears the variable *x*, freeing or recycling its allocated memory.

## 9.4.3 Special values

void **fmpr\_zero**(*fmpr\_t* *x*)

void **fmpr\_one**(*fmpr\_t* *x*)

void **fmpr\_pos\_inf**(*fmpr\_t* *x*)

void **fmpr\_neg\_inf**(*fmpr\_t* *x*)

void **fmpr\_nan**(*fmpr\_t* *x*)

Sets *x* respectively to 0, 1,  $+\infty$ ,  $-\infty$ , NaN.

int **fmpr\_is\_zero**(const *fmpr\_t* *x*)

int **fmpr\_is\_one**(const *fmpr\_t* *x*)

int **fmpr\_is\_pos\_inf**(const *fmpr\_t* *x*)

int **fmpr\_is\_neg\_inf**(const *fmpr\_t* *x*)

int **fmpr\_is\_nan**(const *fmpr\_t* *x*)

Returns nonzero iff *x* respectively equals 0, 1,  $+\infty$ ,  $-\infty$ , NaN.

int **fmpr\_is\_inf**(const *fmpr\_t* *x*)

Returns nonzero iff *x* equals either  $+\infty$  or  $-\infty$ .

`int fmp_r_is_normal(const fmp_r_t x)`  
 Returns nonzero iff  $x$  is a finite, nonzero floating-point value, i.e. not one of the special values 0,  $+\infty$ ,  $-\infty$ , NaN.

`int fmp_r_is_special(const fmp_r_t x)`  
 Returns nonzero iff  $x$  is one of the special values 0,  $+\infty$ ,  $-\infty$ , NaN, i.e. not a finite, nonzero floating-point value.

`int fmp_r_is_finite(fmp_r_t x)`  
 Returns nonzero iff  $x$  is a finite floating-point value, i.e. not one of the values  $+\infty$ ,  $-\infty$ , NaN. (Note that this is not equivalent to the negation of `fmp_r_is_inf()`.)

#### 9.4.4 Assignment, rounding and conversions

`slong fmp_r_normalise(fmpz_t man, fmpz_t exp, slong prec, fmp_rnd_t rnd)`  
 Rounds the mantissa and exponent in-place.

`void fmp_r_set(fmp_r_t y, const fmp_r_t x)`  
 Sets  $y$  to a copy of  $x$ .

`void fmp_r_swap(fmp_r_t x, fmp_r_t y)`  
 Swaps  $x$  and  $y$  efficiently.

`slong fmp_r_set_round(fmp_r_t y, const fmp_r_t x, slong prec, fmp_rnd_t rnd)`

`slong fmp_r_set_round_fmpz(fmp_r_t x, const fmpz_t x, slong prec, fmp_rnd_t rnd)`  
 Sets  $y$  to a copy of  $x$  rounded in the direction specified by `rnd` to the number of bits specified by `prec`.

`slong fmp_r_set_round_mpn(slong * shift, fmpz_t man, mp_srcptr x, mp_size_t xn, int negative, slong prec, fmp_rnd_t rnd)`  
 Given an integer represented by a pointer  $x$  to a raw array of  $xn$  limbs (negated if `negative` is nonzero), sets  $man$  to the corresponding floating-point mantissa rounded to `prec` bits in direction `rnd`, sets `shift` to the exponent, and returns the error bound. We require that  $xn$  is positive and that the leading limb of  $x$  is nonzero.

`slong fmp_r_set_round_ui_2exp_fmpz(fmp_r_t z, mp_limb_t lo, const fmpz_t exp, int negative, slong prec, fmp_rnd_t rnd)`  
 Sets  $z$  to the unsigned integer  $lo$  times two to the power `exp`, negating the value if `negative` is nonzero, and rounding the result to `prec` bits in direction `rnd`.

`slong fmp_r_set_round_uiui_2exp_fmpz(fmp_r_t z, mp_limb_t hi, mp_limb_t lo, const fmpz_t exp, int negative, slong prec, fmp_rnd_t rnd)`  
 Sets  $z$  to the unsigned two-limb integer  $\{hi, lo\}$  times two to the power `exp`, negating the value if `negative` is nonzero, and rounding the result to `prec` bits in direction `rnd`.

`void fmp_r_set_error_result(fmp_r_t err, const fmp_r_t result, slong rret)`  
 Given the return value `rret` and output variable `result` from a function performing a rounding (e.g. `fmp_r_set_round` or `fmp_r_add`), sets `err` to a bound for the absolute error.

`void fmp_r_add_error_result(fmp_r_t err, const fmp_r_t err_in, const fmp_r_t result, slong rret, slong prec, fmp_rnd_t rnd)`  
 Like `fmp_r_set_error_result`, but adds `err_in` to the error.

`void fmp_r_ulp(fmp_r_t u, const fmp_r_t x, slong prec)`  
 Sets  $u$  to the floating-point unit in the last place (ulp) of  $x$ . The ulp is defined as in the MPFR documentation and satisfies  $2^{-n}|x| < u \leq 2^{-n+1}|x|$  for any finite nonzero  $x$ . If  $x$  is a special value,  $u$  is set to the absolute value of  $x$ .

`int fmp_r_check_ulp(const fmp_r_t x, slong r, slong prec)`  
 Assume that  $r$  is the return code and  $x$  is the floating-point result from a single floating-point rounding. Then this function returns nonzero iff  $x$  and  $r$  define an error of exactly 0 or 1 ulp. In other words, this function checks that `fmp_r_set_error_result()` gives exactly 0 or 1 ulp as expected.

`int fmpfr_get_mpfpr(mpfpr_t x, const fmpfr_t y, mpfr_rnd_t rnd)`  
Sets the MPFR variable `x` to the value of `y`. If the precision of `x` is too small to allow `y` to be represented exactly, it is rounded in the specified MPFR rounding mode. The return value indicates the direction of rounding, following the standard convention of the MPFR library.

`void fmpfr_set_mpfpr(fmpfr_t x, const mpfr_t y)`  
Sets `x` to the exact value of the MPFR variable `y`.

`double fmpfr_get_d(const fmpfr_t x, fmpfr_rnd_t rnd)`  
Returns `x` rounded to a *double* in the direction specified by `rnd`.

`void fmpfr_set_d(fmpfr_t x, double v)`  
Sets `x` the the exact value of the argument `v` of type *double*.

`void fmpfr_set_ui(fmpfr_t x, ulong c)`

`void fmpfr_set_si(fmpfr_t x, slong c)`

`void fmpfr_set_fmpz(fmpfr_t x, const fmpz_t c)`  
Sets `x` exactly to the integer `c`.

`void fmpfr_get_fmpz(fmpz_t z, const fmpfr_t x, fmpfr_rnd_t rnd)`  
Sets `z` to `x` rounded to the nearest integer in the direction specified by `rnd`. If `rnd` is `FMPR_RND_NEAR`, rounds to the nearest even integer in case of a tie. Aborts if `x` is infinite, NaN or if the exponent is unreasonably large.

*slong* `fmpfr_get_si(const fmpfr_t x, fmpfr_rnd_t rnd)`  
Returns `x` rounded to the nearest integer in the direction specified by `rnd`. If `rnd` is `FMPR_RND_NEAR`, rounds to the nearest even integer in case of a tie. Aborts if `x` is infinite, NaN, or the value is too large to fit in an *slong*.

`void fmpfr_get_fmpq(fmpq_t y, const fmpfr_t x)`  
Sets `y` to the exact value of `x`. The result is undefined if `x` is not a finite fraction.

*slong* `fmpfr_set_fmpq(fmpfr_t x, const fmpq_t y, slong prec, fmpfr_rnd_t rnd)`  
Sets `x` to the value of `y`, rounded according to `prec` and `rnd`.

`void fmpfr_set_fmpz_2exp(fmpfr_t x, const fmpz_t man, const fmpz_t exp)`

`void fmpfr_set_si_2exp_si(fmpfr_t x, slong man, slong exp)`

`void fmpfr_set_ui_2exp_si(fmpfr_t x, ulong man, slong exp)`  
Sets `x` to  $\text{man} \times 2^{\text{exp}}$ .

*slong* `fmpfr_set_round_fmpz_2exp(fmpfr_t x, const fmpz_t man, const fmpz_t exp, slong prec, fmpfr_rnd_t rnd)`  
Sets `x` to  $\text{man} \times 2^{\text{exp}}$ , rounded according to `prec` and `rnd`.

`void fmpfr_get_fmpz_2exp(fmpz_t man, fmpz_t exp, const fmpfr_t x)`  
Sets `man` and `exp` to the unique integers such that  $x = \text{man} \times 2^{\text{exp}}$  and `man` is odd, provided that `x` is a nonzero finite fraction. If `x` is zero, both `man` and `exp` are set to zero. If `x` is infinite or NaN, the result is undefined.

`int fmpfr_get_fmpz_fixed_fmpz(fmpz_t y, const fmpfr_t x, const fmpz_t e)`

`int fmpfr_get_fmpz_fixed_si(fmpz_t y, const fmpfr_t x, slong e)`  
Converts `x` to a mantissa with predetermined exponent, i.e. computes an integer `y` such that  $y \times 2^e \approx x$ , truncating if necessary. Returns 0 if exact and 1 if truncation occurred.

### 9.4.5 Comparisons

`int fmpfr_equal(const fmpfr_t x, const fmpfr_t y)`  
Returns nonzero iff `x` and `y` are exactly equal. This function does not treat NaN specially, i.e. NaN compares as equal to itself.

int **fmp\_r\_cmp**(const *fmp\_r\_t* *x*, const *fmp\_r\_t* *y*)  
 Returns negative, zero, or positive, depending on whether *x* is respectively smaller, equal, or greater compared to *y*. Comparison with NaN is undefined.

int **fmp\_r\_cmpabs**(const *fmp\_r\_t* *x*, const *fmp\_r\_t* *y*)

int **fmp\_r\_cmpabs\_ui**(const *fmp\_r\_t* *x*, *ulong* *y*)  
 Compares the absolute values of *x* and *y*.

int **fmp\_r\_cmp\_2exp\_si**(const *fmp\_r\_t* *x*, *slong* *e*)

int **fmp\_r\_cmpabs\_2exp\_si**(const *fmp\_r\_t* *x*, *slong* *e*)  
 Compares *x* (respectively its absolute value) with  $2^e$ .

int **fmp\_r\_sgn**(const *fmp\_r\_t* *x*)  
 Returns -1, 0 or +1 according to the sign of *x*. The sign of NaN is undefined.

void **fmp\_r\_min**(*fmp\_r\_t* *z*, const *fmp\_r\_t* *a*, const *fmp\_r\_t* *b*)

void **fmp\_r\_max**(*fmp\_r\_t* *z*, const *fmp\_r\_t* *a*, const *fmp\_r\_t* *b*)  
 Sets *z* respectively to the minimum and the maximum of *a* and *b*.

*slong* **fmp\_r\_bits**(const *fmp\_r\_t* *x*)  
 Returns the number of bits needed to represent the absolute value of the mantissa of *x*, i.e. the minimum precision sufficient to represent *x* exactly. Returns 0 if *x* is a special value.

int **fmp\_r\_is\_int**(const *fmp\_r\_t* *x*)  
 Returns nonzero iff *x* is integer-valued.

int **fmp\_r\_is\_int\_2exp\_si**(const *fmp\_r\_t* *x*, *slong* *e*)  
 Returns nonzero iff *x* equals  $n2^e$  for some integer *n*.

void **fmp\_r\_abs\_bound\_le\_2exp\_fmpz**(*fmpz\_t* *b*, const *fmp\_r\_t* *x*)  
 Sets *b* to the smallest integer such that  $|x| \leq 2^b$ . If *x* is zero, infinity or NaN, the result is undefined.

void **fmp\_r\_abs\_bound\_lt\_2exp\_fmpz**(*fmpz\_t* *b*, const *fmp\_r\_t* *x*)  
 Sets *b* to the smallest integer such that  $|x| < 2^b$ . If *x* is zero, infinity or NaN, the result is undefined.

*slong* **fmp\_r\_abs\_bound\_lt\_2exp\_si**(const *fmp\_r\_t* *x*)  
 Returns the smallest integer *b* such that  $|x| < 2^b$ , clamping the result to lie between `-FMPR_PREC_EXACT` and `FMPR_PREC_EXACT` inclusive. If *x* is zero, `-FMPR_PREC_EXACT` is returned, and if *x* is infinity or NaN, `FMPR_PREC_EXACT` is returned.

## 9.4.6 Random number generation

void **fmp\_r\_randtest**(*fmp\_r\_t* *x*, *flint\_rand\_t* *state*, *slong* *bits*, *slong* *mag\_bits*)  
 Generates a finite random number whose mantissa has precision at most *bits* and whose exponent has at most *mag\_bits* bits. The values are distributed non-uniformly: special bit patterns are generated with high probability in order to allow the test code to exercise corner cases.

void **fmp\_r\_randtest\_not\_zero**(*fmp\_r\_t* *x*, *flint\_rand\_t* *state*, *slong* *bits*, *slong* *mag\_bits*)  
 Identical to *fmp\_r\_randtest*, except that zero is never produced as an output.

void **fmp\_r\_randtest\_special**(*fmp\_r\_t* *x*, *flint\_rand\_t* *state*, *slong* *bits*, *slong* *mag\_bits*)  
 Identical to *fmp\_r\_randtest*, except that the output occasionally is set to an infinity or NaN.

## 9.4.7 Input and output

void **fmp\_r\_print**(const *fmp\_r\_t* *x*)  
 Prints the mantissa and exponent of *x* as integers, precisely showing the internal representation.

void **fmp<sub>r</sub>\_prntd**(const *fmp<sub>r</sub>\_t* *x*, *slong* *digits*)

Prints *x* as a decimal floating-point number, rounding to the specified number of digits. This function is currently implemented using MPFR, and does not support large exponents.

### 9.4.8 Arithmetic

void **fmp<sub>r</sub>\_neg**(*fmp<sub>r</sub>\_t* *y*, const *fmp<sub>r</sub>\_t* *x*)

Sets *y* to the negation of *x*.

*slong* **fmp<sub>r</sub>\_neg\_round**(*fmp<sub>r</sub>\_t* *y*, const *fmp<sub>r</sub>\_t* *x*, *slong* *prec*, *fmp<sub>r</sub>\_rnd\_t* *rnd*)

Sets *y* to the negation of *x*, rounding the result.

void **fmp<sub>r</sub>\_abs**(*fmp<sub>r</sub>\_t* *y*, const *fmp<sub>r</sub>\_t* *x*)

Sets *y* to the absolute value of *x*.

*slong* **fmp<sub>r</sub>\_add**(*fmp<sub>r</sub>\_t* *z*, const *fmp<sub>r</sub>\_t* *x*, const *fmp<sub>r</sub>\_t* *y*, *slong* *prec*, *fmp<sub>r</sub>\_rnd\_t* *rnd*)

*slong* **fmp<sub>r</sub>\_add\_ui**(*fmp<sub>r</sub>\_t* *z*, const *fmp<sub>r</sub>\_t* *x*, *ulong* *y*, *slong* *prec*, *fmp<sub>r</sub>\_rnd\_t* *rnd*)

*slong* **fmp<sub>r</sub>\_add\_si**(*fmp<sub>r</sub>\_t* *z*, const *fmp<sub>r</sub>\_t* *x*, *slong* *y*, *slong* *prec*, *fmp<sub>r</sub>\_rnd\_t* *rnd*)

*slong* **fmp<sub>r</sub>\_add\_fmpz**(*fmp<sub>r</sub>\_t* *z*, const *fmp<sub>r</sub>\_t* *x*, const *fmpz\_t* *y*, *slong* *prec*, *fmp<sub>r</sub>\_rnd\_t* *rnd*)

Sets  $z = x + y$ , rounded according to *prec* and *rnd*. The precision can be *FMPR\_PREC\_EXACT* to perform an exact addition, provided that the result fits in memory.

*slong* **\_fmp<sub>r</sub>\_add\_eps**(*fmp<sub>r</sub>\_t* *z*, const *fmp<sub>r</sub>\_t* *x*, int *sign*, *slong* *prec*, *fmp<sub>r</sub>\_rnd\_t* *rnd*)

Sets *z* to the value that results by adding an infinitesimal quantity of the given sign to *x*, and rounding. The result is undefined if *x* is zero.

*slong* **fmp<sub>r</sub>\_sub**(*fmp<sub>r</sub>\_t* *z*, const *fmp<sub>r</sub>\_t* *x*, const *fmp<sub>r</sub>\_t* *y*, *slong* *prec*, *fmp<sub>r</sub>\_rnd\_t* *rnd*)

*slong* **fmp<sub>r</sub>\_sub\_ui**(*fmp<sub>r</sub>\_t* *z*, const *fmp<sub>r</sub>\_t* *x*, *ulong* *y*, *slong* *prec*, *fmp<sub>r</sub>\_rnd\_t* *rnd*)

*slong* **fmp<sub>r</sub>\_sub\_si**(*fmp<sub>r</sub>\_t* *z*, const *fmp<sub>r</sub>\_t* *x*, *slong* *y*, *slong* *prec*, *fmp<sub>r</sub>\_rnd\_t* *rnd*)

*slong* **fmp<sub>r</sub>\_sub\_fmpz**(*fmp<sub>r</sub>\_t* *z*, const *fmp<sub>r</sub>\_t* *x*, const *fmpz\_t* *y*, *slong* *prec*, *fmp<sub>r</sub>\_rnd\_t* *rnd*)

Sets  $z = x - y$ , rounded according to *prec* and *rnd*. The precision can be *FMPR\_PREC\_EXACT* to perform an exact addition, provided that the result fits in memory.

*slong* **fmp<sub>r</sub>\_sum**(*fmp<sub>r</sub>\_t* *s*, const *fmp<sub>r</sub>\_struct* \* *terms*, *slong* *len*, *slong* *prec*, *fmp<sub>r</sub>\_rnd\_t* *rnd*)

Sets *s* to the sum of the array *terms* of length *len*, rounded to *prec* bits in the direction *rnd*. The sum is computed as if done without any intermediate rounding error, with only a single rounding applied to the final result. Unlike repeated calls to *fmp<sub>r</sub>\_add*, this function does not overflow if the magnitudes of the terms are far apart. Warning: this function is implemented naively, and the running time is quadratic with respect to *len* in the worst case.

*slong* **fmp<sub>r</sub>\_mul**(*fmp<sub>r</sub>\_t* *z*, const *fmp<sub>r</sub>\_t* *x*, const *fmp<sub>r</sub>\_t* *y*, *slong* *prec*, *fmp<sub>r</sub>\_rnd\_t* *rnd*)

*slong* **fmp<sub>r</sub>\_mul\_ui**(*fmp<sub>r</sub>\_t* *z*, const *fmp<sub>r</sub>\_t* *x*, *ulong* *y*, *slong* *prec*, *fmp<sub>r</sub>\_rnd\_t* *rnd*)

*slong* **fmp<sub>r</sub>\_mul\_si**(*fmp<sub>r</sub>\_t* *z*, const *fmp<sub>r</sub>\_t* *x*, *slong* *y*, *slong* *prec*, *fmp<sub>r</sub>\_rnd\_t* *rnd*)

*slong* **fmp<sub>r</sub>\_mul\_fmpz**(*fmp<sub>r</sub>\_t* *z*, const *fmp<sub>r</sub>\_t* *x*, const *fmpz\_t* *y*, *slong* *prec*, *fmp<sub>r</sub>\_rnd\_t* *rnd*)

Sets  $z = x \times y$ , rounded according to *prec* and *rnd*. The precision can be *FMPR\_PREC\_EXACT* to perform an exact multiplication, provided that the result fits in memory.

void **fmp<sub>r</sub>\_mul\_2exp\_si**(*fmp<sub>r</sub>\_t* *y*, const *fmp<sub>r</sub>\_t* *x*, *slong* *e*)

void **fmp<sub>r</sub>\_mul\_2exp\_fmpz**(*fmp<sub>r</sub>\_t* *y*, const *fmp<sub>r</sub>\_t* *x*, const *fmpz\_t* *e*)

Sets *y* to *x* multiplied by  $2^e$  without rounding.

*slong* **fmp<sub>r</sub>\_div**(*fmp<sub>r</sub>\_t* *z*, const *fmp<sub>r</sub>\_t* *x*, const *fmp<sub>r</sub>\_t* *y*, *slong* *prec*, *fmp<sub>r</sub>\_rnd\_t* *rnd*)

*slong* **fmp<sub>r</sub>\_div\_ui**(*fmp<sub>r</sub>\_t* *z*, const *fmp<sub>r</sub>\_t* *x*, *ulong* *y*, *slong* *prec*, *fmp<sub>r</sub>\_rnd\_t* *rnd*)

*slong* **fmp<sub>r</sub>\_ui\_div**(*fmp<sub>r</sub>\_t* *z*, *ulong* *x*, const *fmp<sub>r</sub>\_t* *y*, *slong* *prec*, *fmp<sub>r</sub>\_rnd\_t* *rnd*)

*slong* **fmp<sub>r</sub>\_div\_si**(*fmp<sub>r</sub>\_t* *z*, const *fmp<sub>r</sub>\_t* *x*, *slong* *y*, *slong* *prec*, *fmp<sub>r</sub>\_rnd\_t* *rnd*)

*slong fmpz\_si\_div*(*fmpz\_t* z, *slong* x, const *fmpz\_t* y, *slong* prec, *fmpz\_rnd\_t* rnd)

*slong fmpz\_div\_fmpz*(*fmpz\_t* z, const *fmpz\_t* x, const *fmpz\_t* y, *slong* prec, *fmpz\_rnd\_t* rnd)

*slong fmpz\_fmpz\_div*(*fmpz\_t* z, const *fmpz\_t* x, const *fmpz\_t* y, *slong* prec, *fmpz\_rnd\_t* rnd)

*slong fmpz\_fmpz\_div\_fmpz*(*fmpz\_t* z, const *fmpz\_t* x, const *fmpz\_t* y, *slong* prec, *fmpz\_rnd\_t* rnd)

Sets  $z = x/y$ , rounded according to *prec* and *rnd*. If *y* is zero, *z* is set to NaN.

void *fmpz\_divappr\_abs\_ubound*(*fmpz\_t* z, const *fmpz\_t* x, const *fmpz\_t* y, *slong* prec)

Sets *z* to an upper bound for  $|x|/|y|$ , computed to a precision of approximately *prec* bits. The error can be a few ulp.

*slong fmpz\_addmul*(*fmpz\_t* z, const *fmpz\_t* x, const *fmpz\_t* y, *slong* prec, *fmpz\_rnd\_t* rnd)

*slong fmpz\_addmul\_ui*(*fmpz\_t* z, const *fmpz\_t* x, *ulong* y, *slong* prec, *fmpz\_rnd\_t* rnd)

*slong fmpz\_addmul\_si*(*fmpz\_t* z, const *fmpz\_t* x, *slong* y, *slong* prec, *fmpz\_rnd\_t* rnd)

*slong fmpz\_addmul\_fmpz*(*fmpz\_t* z, const *fmpz\_t* x, const *fmpz\_t* y, *slong* prec, *fmpz\_rnd\_t* rnd)

Sets  $z = z + x \times y$ , rounded according to *prec* and *rnd*. The intermediate multiplication is always performed without roundoff. The precision can be *FMPZ\_PREC\_EXACT* to perform an exact addition, provided that the result fits in memory.

*slong fmpz\_submul*(*fmpz\_t* z, const *fmpz\_t* x, const *fmpz\_t* y, *slong* prec, *fmpz\_rnd\_t* rnd)

*slong fmpz\_submul\_ui*(*fmpz\_t* z, const *fmpz\_t* x, *ulong* y, *slong* prec, *fmpz\_rnd\_t* rnd)

*slong fmpz\_submul\_si*(*fmpz\_t* z, const *fmpz\_t* x, *slong* y, *slong* prec, *fmpz\_rnd\_t* rnd)

*slong fmpz\_submul\_fmpz*(*fmpz\_t* z, const *fmpz\_t* x, const *fmpz\_t* y, *slong* prec, *fmpz\_rnd\_t* rnd)

Sets  $z = z - x \times y$ , rounded according to *prec* and *rnd*. The intermediate multiplication is always performed without roundoff. The precision can be *FMPZ\_PREC\_EXACT* to perform an exact subtraction, provided that the result fits in memory.

*slong fmpz\_sqrt*(*fmpz\_t* y, const *fmpz\_t* x, *slong* prec, *fmpz\_rnd\_t* rnd)

*slong fmpz\_sqrt\_ui*(*fmpz\_t* z, *ulong* x, *slong* prec, *fmpz\_rnd\_t* rnd)

*slong fmpz\_sqrt\_fmpz*(*fmpz\_t* z, const *fmpz\_t* x, *slong* prec, *fmpz\_rnd\_t* rnd)

Sets *z* to the square root of *x*, rounded according to *prec* and *rnd*. The result is NaN if *x* is negative.

*slong fmpz\_rsqr*(*fmpz\_t* z, const *fmpz\_t* x, *slong* prec, *fmpz\_rnd\_t* rnd)

Sets *z* to the reciprocal square root of *x*, rounded according to *prec* and *rnd*. The result is NaN if *x* is negative. At high precision, this is faster than computing a square root.

*slong fmpz\_root*(*fmpz\_t* z, const *fmpz\_t* x, *ulong* k, *slong* prec, *fmpz\_rnd\_t* rnd)

Sets *z* to the *k*-th root of *x*, rounded to *prec* bits in the direction *rnd*. Warning: this function wraps MPFR, and is currently only fast for small *k*.

void *fmpz\_pow\_sloppy\_fmpz*(*fmpz\_t* y, const *fmpz\_t* b, const *fmpz\_t* e, *slong* prec, *fmpz\_rnd\_t* rnd)

void *fmpz\_pow\_sloppy\_ui*(*fmpz\_t* y, const *fmpz\_t* b, *ulong* e, *slong* prec, *fmpz\_rnd\_t* rnd)

void *fmpz\_pow\_sloppy\_si*(*fmpz\_t* y, const *fmpz\_t* b, *slong* e, *slong* prec, *fmpz\_rnd\_t* rnd)

Sets  $y = b^e$ , computed using without guaranteeing correct (optimal) rounding, but guaranteeing that the result is a correct upper or lower bound if the rounding is directional. Currently requires  $b \geq 0$ .

### 9.4.9 Special functions

*slong fmpz\_log*(*fmpz\_t* y, const *fmpz\_t* x, *slong* prec, *fmpz\_rnd\_t* rnd)

Sets *y* to  $\log(x)$ , rounded according to *prec* and *rnd*. The result is NaN if *x* is negative. This function is currently implemented using MPFR and does not support large exponents.

*slong* **fmpfr\_log1p**(*fmpfr\_t* y, const *fmpfr\_t* x, *slong* prec, *fmpfr\_rnd\_t* rnd)

Sets *y* to  $\log(1+x)$ , rounded according to *prec* and *rnd*. This function computes an accurate value when *x* is small. The result is NaN if  $1+x$  is negative. This function is currently implemented using MPFR and does not support large exponents.

*slong* **fmpfr\_exp**(*fmpfr\_t* y, const *fmpfr\_t* x, *slong* prec, *fmpfr\_rnd\_t* rnd)

Sets *y* to  $\exp(x)$ , rounded according to *prec* and *rnd*. This function is currently implemented using MPFR and does not support large exponents.

*slong* **fmpfr\_expn1**(*fmpfr\_t* y, const *fmpfr\_t* x, *slong* prec, *fmpfr\_rnd\_t* rnd)

Sets *y* to  $\exp(x) - 1$ , rounded according to *prec* and *rnd*. This function computes an accurate value when *x* is small. This function is currently implemented using MPFR and does not support large exponents.

## SUPPLEMENTARY ALGORITHM NOTES

Here, we give extra proofs, error bounds, and formulas that would be too lengthy to reproduce in the documentation for each module.

### 10.1 General formulas and bounds

This section collects some results from real and complex analysis that are useful when deriving error bounds. Beware of typos.

#### 10.1.1 Error propagation

We want to bound the error when  $f(x+a)$  is approximated by  $f(x)$ . Specifically, the goal is to bound  $f(x+a) - f(x)$  in terms of  $r$  for the set of values  $a$  with  $|a| \leq r$ . Most bounds will be monotone increasing with  $|a|$  (assuming that  $x$  is fixed), so for brevity we simply express the bounds in terms of  $|a|$ .

**Theorem (generic first-order bound):**

$$|f(x+a) - f(x)| \leq \min(2C_0, C_1|a|)$$

where

$$C_0 = \sup_{|t| \leq |a|} |f(x+t)|, \quad C_1 = \sup_{|t| \leq |a|} |f'(x+t)|.$$

The statement is valid with either  $a, t \in \mathbb{R}$  or  $a, t \in \mathbb{C}$ .

**Theorem (product):** For  $x, y \in \mathbb{C}$  and  $a, b \in \mathbb{C}$ ,

$$|(x+a)(y+b) - xy| \leq |xb| + |ya| + |ab|.$$

**Theorem (quotient):** For  $x, y \in \mathbb{C}$  and  $a, b \in \mathbb{C}$  with  $|b| < |y|$ ,

$$\left| \frac{x}{y} - \frac{x+a}{y+b} \right| \leq \frac{|xb| + |ya|}{|y|(|y| - |b|)}.$$

**Theorem (square root):** For  $x, a \in \mathbb{R}$  with  $0 \leq |a| \leq x$ ,

$$|\sqrt{x+a} - \sqrt{x}| \leq \sqrt{x} \left( 1 - \sqrt{1 - \frac{|a|}{x}} \right) \leq \frac{\sqrt{x}}{2} \left( \frac{|a|}{x} + \frac{|a|^2}{x^2} \right)$$

where the first inequality is an equality if  $a \leq 0$ . (When  $x = a = 0$ , the limiting value is 0.)

**Theorem (reciprocal square root):** For  $x, a \in \mathbb{R}$  with  $0 \leq |a| < x$ ,

$$\left| \frac{1}{\sqrt{x+a}} - \frac{1}{\sqrt{x}} \right| \leq \frac{|a|}{2(x-|a|)^{3/2}}.$$

**Theorem (k-th root):** For  $k > 1$  and  $x, a \in \mathbb{R}$  with  $0 \leq |a| \leq x$ ,

$$\left| (x+a)^{1/k} - x^{1/k} \right| \leq x^{1/k} \min \left( 1, \frac{1}{k} \log \left( 1 + \frac{|a|}{x-|a|} \right) \right).$$

*Proof:* The error is largest when  $a = -r$  is negative, and

$$\begin{aligned} x^{1/k} - (x-r)^{1/k} &= x^{1/k} [1 - (1-r/x)^{1/k}] \\ &= x^{1/k} [1 - \exp(\log(1-r/x)/k)] \leq x^{1/k} \min(1, -\log(1-r/x)/k) \\ &= x^{1/k} \min(1, \log(1+r/(x-r))/k). \end{aligned}$$

**Theorem (sine, cosine):** For  $x, a \in \mathbb{R}$ ,  $|\sin(x+a) - \sin(x)| \leq \min(2, |a|)$ .

**Theorem (logarithm):** For  $x, a \in \mathbb{R}$  with  $0 \leq |a| < x$ ,

$$|\log(x+a) - \log(x)| \leq \log \left( 1 + \frac{|a|}{x-|a|} \right),$$

with equality if  $a \leq 0$ .

**Theorem (exponential):** For  $x, a \in \mathbb{R}$ ,  $|e^{x+a} - e^x| = e^x(e^a - 1) \leq e^x(e^{|a|} - 1)$ , with equality if  $a \geq 0$ .

**Theorem (inverse tangent):** For  $x, a \in \mathbb{R}$ ,

$$|\operatorname{atan}(x+a) - \operatorname{atan}(x)| \leq \min(\pi, C_1|a|).$$

where

$$C_1 = \sup_{|t| \leq |a|} \frac{1}{1 + (x+t)^2}.$$

If  $|a| < |x|$ , then  $C_1 = (1 + (|x| - |a|)^2)^{-1}$  gives a monotone bound.

An exact bound: if  $|a| < |x|$  or  $|x(x+a)| < 1$ , then

$$|\operatorname{atan}(x+a) - \operatorname{atan}(x)| = \operatorname{atan} \left( \frac{|a|}{1 + x(x+a)} \right).$$

In the last formula, a case distinction has to be made depending on the signs of  $x$  and  $a$ .

### 10.1.2 Sums and series

**Theorem (geometric bound):** If  $|c_k| \leq C$  and  $|z| \leq D < 1$ , then

$$\left| \sum_{k=N}^{\infty} c_k z^k \right| \leq \frac{CD^N}{1-D}.$$

**Theorem (integral bound):** If  $f(x)$  is nonnegative and monotone decreasing, then

$$\int_N^{\infty} f(x) \leq \sum_{k=N}^{\infty} f(k) \leq f(N) + \int_N^{\infty} f(x) dx.$$

### 10.1.3 Complex analytic functions

**Theorem (Cauchy's integral formula):** If  $f(z) = \sum_{k=0}^{\infty} c_k z^k$  is analytic (on an open subset of  $\mathbb{C}$  containing the disk  $D = \{z : |z| \leq R\}$  in its interior, where  $R > 0$ ), then

$$c_k = \frac{1}{2\pi i} \int_{|z|=R} \frac{f(z)}{z^{k+1}} dz.$$

**Corollary (derivative bound):**

$$|c_k| \leq \frac{C}{R^k}, \quad C = \max_{|z|=R} |f(z)|.$$

**Corollary (Taylor series tail):** If  $0 \leq r < R$  and  $|z| \leq r$ , then

$$\left| \sum_{k=N}^{\infty} c_k z^k \right| \leq \frac{CD^N}{1-D}, \quad D = \left| \frac{r}{R} \right|.$$

### 10.1.4 Euler-Maclaurin formula

**Theorem (Euler-Maclaurin):** If  $f(t)$  is  $2M$ -times differentiable, then

$$\begin{aligned} \sum_{k=L}^U f(k) &= S + I + T + R \\ S &= \sum_{k=L}^{N-1} f(k), \quad I = \int_N^U f(t) dt, \\ T &= \frac{1}{2} (f(N) + f(U)) + \sum_{k=1}^M \frac{B_{2k}}{(2k)!} \left( f^{(2k-1)}(U) - f^{(2k-1)}(N) \right), \\ R &= - \int_N^U \frac{B_{2M}(t - \lfloor t \rfloor)}{(2M)!} f^{(2M)}(t) dt. \end{aligned}$$

**Lemma (Bernoulli polynomials):**  $|B_n(t - \lfloor t \rfloor)| \leq 4n!/(2\pi)^n$ .

**Theorem (remainder bound):**

$$|R| \leq \frac{4}{(2\pi)^{2M}} \int_N^U |f^{(2M)}(t)| dt.$$

**Theorem (parameter derivatives):** If  $f(t) = f(t, x) = \sum_{k=0}^{\infty} a_k(t) x^k$  and  $R = R(x) = \sum_{k=0}^{\infty} c_k x^k$  are analytic functions of  $x$ , then

$$|c_k| \leq \frac{4}{(2\pi)^{2M}} \int_N^U |a_k^{(2M)}(t)| dt.$$

## 10.2 Algorithms for mathematical constants

Most mathematical constants are evaluated using the generic hypergeometric summation code.

### 10.2.1 Pi

$\pi$  is computed using the Chudnovsky series

$$\frac{1}{\pi} = 12 \sum_{k=0}^{\infty} \frac{(-1)^k (6k)! (13591409 + 545140134k)}{(3k)! (k!)^3 640320^{3k+3/2}}$$

which is hypergeometric and adds roughly 14 digits per term. Methods based on the arithmetic-geometric mean seem to be slower by a factor three in practice.

A small trick is to compute  $1/\sqrt{640320}$  instead of  $\sqrt{640320}$  at the end.

### 10.2.2 Logarithms of integers

We use the formulas

$$\log(2) = \frac{3}{4} \sum_{k=0}^{\infty} \frac{(-1)^k (k!)^2}{2^k (2k+1)!}$$

$$\log(10) = 46 \operatorname{atanh}(1/31) + 34 \operatorname{atanh}(1/49) + 20 \operatorname{atanh}(1/161)$$

### 10.2.3 Euler's constant

Euler's constant  $\gamma$  is computed using the Brent-McMillan formula ([BM1980], [MPFR2012])

$$\gamma = \frac{S_0(2n) - K_0(2n)}{I_0(2n)} - \log(n)$$

in which  $n$  is a free parameter and

$$S_0(x) = \sum_{k=0}^{\infty} \frac{H_k}{(k!)^2} \left(\frac{x}{2}\right)^{2k}, \quad I_0(x) = \sum_{k=0}^{\infty} \frac{1}{(k!)^2} \left(\frac{x}{2}\right)^{2k}$$

$$2xI_0(x)K_0(x) \sim \sum_{k=0}^{\infty} \frac{[(2k)!]^3}{(k!)^4 8^{2k} x^{2k}}.$$

All series are evaluated using binary splitting. The first two series are evaluated simultaneously, with the summation taken up to  $k = N - 1$  inclusive where  $N \geq \alpha n + 1$  and  $\alpha \approx 4.9706257595442318644$  satisfies  $\alpha(\log \alpha - 1) = 3$ . The third series is taken up to  $k = 2n - 1$  inclusive. With these parameters, it is shown in [BJ2013] that the error is bounded by  $24e^{-8n}$ .

### 10.2.4 Catalan's constant

Catalan's constant is computed using the hypergeometric series

$$C = \sum_{k=0}^{\infty} \frac{(-1)^k 4^{4k+1} (40k^2 + 56k + 19) [(k+1)!]^2 [(2k+2)!]^3}{(k+1)^3 (2k+1) [(4k+4)!]^2}$$

### 10.2.5 Khinchin's constant

Khinchin's constant  $K_0$  is computed using the formula

$$\log K_0 = \frac{1}{\log 2} \left[ \sum_{k=2}^{N-1} \log \left( \frac{k-1}{k} \right) \log \left( \frac{k+1}{k} \right) + \sum_{n=1}^{\infty} \frac{\zeta(2n, N)}{n} \sum_{k=1}^{2n-1} \frac{(-1)^{k+1}}{k} \right]$$

where  $N \geq 2$  is a free parameter that can be used for tuning [BBC1997]. If the infinite series is truncated after  $n = M$ , the remainder is smaller in absolute value than

$$\begin{aligned} \sum_{n=M+1}^{\infty} \zeta(2n, N) &= \sum_{n=M+1}^{\infty} \sum_{k=0}^{\infty} (k+N)^{-2n} \leq \sum_{n=M+1}^{\infty} \left( N^{-2n} + \int_0^{\infty} (t+N)^{-2n} dt \right) \\ &= \sum_{n=M+1}^{\infty} \frac{1}{N^{2n}} \left( 1 + \frac{N}{2n-1} \right) \leq \sum_{n=M+1}^{\infty} \frac{N+1}{N^{2n}} = \frac{1}{N^{2M}(N-1)} \leq \frac{1}{N^{2M}}. \end{aligned}$$

Thus, for an error of at most  $2^{-p}$  in the series, it is sufficient to choose  $M \geq p/(2 \log_2 N)$ .

## 10.2.6 Glaisher's constant

Glaisher's constant  $A = \exp(1/12 - \zeta'(-1))$  is computed directly from this formula. We don't use the reflection formula for the zeta function, as the arithmetic in Euler-Maclaurin summation is faster at  $s = -1$  than at  $s = 2$ .

## 10.2.7 Apéry's constant

Apéry's constant  $\zeta(3)$  is computed using the hypergeometric series

$$\zeta(3) = \frac{1}{64} \sum_{k=0}^{\infty} (-1)^k (205k^2 + 250k + 77) \frac{(k!)^{10}}{[(2k+1)!]^5}.$$

## 10.3 Algorithms for the gamma function

### 10.3.1 The Stirling series

In general, the gamma function is computed via the Stirling series

$$\log \Gamma(z) = \left(z - \frac{1}{2}\right) \log z - z + \frac{\ln 2\pi}{2} + \sum_{k=1}^{n-1} \frac{B_{2k}}{2k(2k-1)z^{2k-1}} + R(n, z)$$

where ([Olv1997] pp. 293-295) the remainder term is exactly

$$R_n(z) = \int_0^{\infty} \frac{B_{2n} - \tilde{B}_{2n}(x)}{2n(x+z)^{2n}} dx.$$

To evaluate the gamma function of a power series argument, we substitute  $z \rightarrow z + t \in \mathbb{C}[[t]]$ .

Using the bound for  $|x + z|$  given by [Olv1997] and the fact that the numerator of the integrand is bounded in absolute value by  $2|B_{2n}|$ , the remainder can be shown to satisfy the bound

$$|[t^k]R_n(z+t)| \leq 2|B_{2n}| \frac{\Gamma(2n+k-1)}{\Gamma(k+1)\Gamma(2n+1)} |z| \left(\frac{b}{|z|}\right)^{2n+k}$$

where  $b = 1/\cos(\arg(z)/2)$ . Note that by trigonometric identities, assuming that  $z = x + yi$ , we have  $b = \sqrt{1+u^2}$  where

$$u = \frac{y}{\sqrt{x^2+y^2}+x} = \frac{\sqrt{x^2+y^2}-x}{y}.$$

To use the Stirling series at  $p$ -bit precision, we select parameters  $r, n$  such that the remainder  $R(n, z)$  approximately is bounded by  $2^{-p}$ . If  $|z|$  is too small for the Stirling series to give sufficient accuracy directly, we first translate to  $z + r$  using the formula  $\Gamma(z) = \Gamma(z+r)/(z(z+1)(z+2)\cdots(z+r-1))$ .

To obtain a remainder smaller than  $2^{-p}$ , we must choose an  $r$  such that, in the real case,  $z + r > \beta p$ , where  $\beta > \log(2)/(2\pi) \approx 0.11$ . In practice, a slightly larger factor  $\beta \approx 0.2$  more closely balances  $n$  and  $r$ . A much larger  $\beta$  (e.g.  $\beta = 1$ ) could be used to reduce the number of Bernoulli numbers that have to be precomputed, at the expense of slower repeated evaluation.

### 10.3.2 Rational arguments

We use efficient methods to compute  $y = \Gamma(p/q)$  where  $q$  is one of 1, 2, 3, 4, 6 and  $p$  is a small integer.

The cases  $\Gamma(1) = 1$  and  $\Gamma(1/2) = \sqrt{\pi}$  are trivial. We reduce all remaining cases to  $\Gamma(1/3)$  or  $\Gamma(1/4)$  using the following relations:

$$\Gamma(2/3) = \frac{2\pi}{3^{1/2}\Gamma(1/3)}, \quad \Gamma(3/4) = \frac{2^{1/2}\pi}{\Gamma(1/4)},$$

$$\Gamma(1/6) = \frac{\Gamma(1/3)^2}{(\pi/3)^{1/2}2^{1/3}}, \quad \Gamma(5/6) = \frac{2\pi(\pi/3)^{1/2}2^{1/3}}{\Gamma(1/3)^2}.$$

We compute  $\Gamma(1/3)$  and  $\Gamma(1/4)$  rapidly to high precision using

$$\Gamma(1/3) = \left( \frac{12\pi^4}{\sqrt{10}} \sum_{k=0}^{\infty} \frac{(6k)!(-1)^k}{(k!)^3(3k)!3^k160^{3k}} \right)^{1/6}, \quad \Gamma(1/4) = \sqrt{\frac{(2\pi)^{3/2}}{\text{agm}(1, \sqrt{2})}}.$$

An alternative formula which could be used for  $\Gamma(1/3)$  is

$$\Gamma(1/3) = \frac{2^{4/9}\pi^{2/3}}{3^{1/12} \left( \text{agm} \left( 1, \frac{1}{2}\sqrt{2+\sqrt{3}} \right) \right)^{1/3}},$$

but this appears to be slightly slower in practice.

## 10.4 Algorithms for the Hurwitz zeta function

### 10.4.1 Euler-Maclaurin summation

The Euler-Maclaurin formula allows evaluating the Hurwitz zeta function and its derivatives for general complex input. The algorithm is described in [Joh2013].

### 10.4.2 Parameter Taylor series

To evaluate  $\zeta(s, a)$  for several nearby parameter values, the following Taylor expansion is useful:

$$\zeta(s, a+x) = \sum_{k=0}^{\infty} (-x)^k \frac{(s)_k}{k!} \zeta(s+k, a)$$

We assume that  $a \geq 1$  is real and that  $\sigma = \text{re}(s)$  with  $K + \sigma > 1$ . The tail is bounded by

$$\sum_{k=K}^{\infty} |x|^k \frac{|(s)_k|}{k!} \zeta(\sigma+k, a) \leq \sum_{k=K}^{\infty} |x|^k \frac{|(s)_k|}{k!} \left[ \frac{1}{a^{\sigma+k}} + \frac{1}{(\sigma+k-1)a^{\sigma+k-1}} \right].$$

Denote the term on the right by  $T(k)$ . Then

$$\left| \frac{T(k+1)}{T(k)} \right| = \frac{|x|}{a} \frac{(k+\sigma-1)}{(k+\sigma)} \frac{(k+\sigma+a)}{(k+\sigma+a-1)} \frac{|k+s|}{(k+1)} \leq \frac{|x|}{a} \left( 1 + \frac{1}{K+\sigma+a-1} \right) \left( 1 + \frac{|s-1|}{K+1} \right) = C$$

and if  $C < 1$ ,

$$\sum_{k=K}^{\infty} T(k) \leq \frac{T(K)}{1-C}.$$

## 10.5 Algorithms for polylogarithms

The polylogarithm is defined for  $s, z \in \mathbb{C}$  with  $|z| < 1$  by

$$\text{Li}_s(z) = \sum_{k=1}^{\infty} \frac{z^k}{k^s}$$

and for  $|z| \geq 1$  by analytic continuation, except for the singular point  $z = 1$ .

### 10.5.1 Computation for small $z$

The power sum converges rapidly when  $|z| \ll 1$ . To compute the series expansion with respect to  $s$ , we substitute  $s \rightarrow s + x \in \mathbb{C}[[x]]$  and obtain

$$\text{Li}_{s+x}(z) = \sum_{d=0}^{\infty} x^d \frac{(-1)^d}{d!} \sum_{k=1}^{\infty} T(k)$$

where

$$T(k) = \frac{z^k \log^d(k)}{k^s}.$$

The remainder term  $|\sum_{k=N}^{\infty} T(k)|$  is bounded via `mag_polylog_tail()`.

### 10.5.2 Expansion for general $z$

For general complex  $s, z$ , we write the polylogarithm as a sum of two Hurwitz zeta functions

$$\text{Li}_s(z) = \frac{\Gamma(v)}{(2\pi)^v} \left[ i^v \zeta \left( v, \frac{1}{2} + \frac{\log(-z)}{2\pi i} \right) + i^{-v} \zeta \left( v, \frac{1}{2} - \frac{\log(-z)}{2\pi i} \right) \right]$$

in which  $s = 1 - v$ . With the principal branch of  $\log(-z)$ , we obtain the conventional analytic continuation of the polylogarithm with a branch cut on  $z \in (1, +\infty)$ .

To compute the series expansion with respect to  $v$ , we substitute  $v \rightarrow v + x \in \mathbb{C}[[x]]$  in this formula (at the end of the computation, we map  $x \rightarrow -x$  to obtain the power series for  $\text{Li}_{s+x}(z)$ ). The right hand side becomes

$$\Gamma(v+x)[E_1 Z_1 + E_2 Z_2]$$

where  $E_1 = (i/(2\pi))^{v+x}$ ,  $Z_1 = \zeta(v+x, \dots)$ ,  $E_2 = (1/(2\pi i))^{v+x}$ ,  $Z_2 = \zeta(v+x, \dots)$ .

When  $v = 1$ , the  $Z_1$  and  $Z_2$  terms become Laurent series with a leading  $1/x$  term. In this case, we compute the deflated series  $\tilde{Z}_1, \tilde{Z}_2 = \zeta(x, \dots) - 1/x$ . Then

$$E_1 Z_1 + E_2 Z_2 = (E_1 + E_2)/x + E_1 \tilde{Z}_1 + E_2 \tilde{Z}_2.$$

Note that  $(E_1 + E_2)/x$  is a power series, since the constant term in  $E_1 + E_2$  is zero when  $v = 1$ . So we simply compute one extra derivative of both  $E_1$  and  $E_2$ , and shift them one step. When  $v = 0, -1, -2, \dots$ , the  $\Gamma(v+x)$  prefactor has a pole. In this case, we proceed analogously and formally multiply  $x \Gamma(v+x)$  with  $[E_1 Z_1 + E_2 Z_2]/x$ .

Note that the formal cancellation only works when the order  $s$  (or  $v$ ) is an exact integer: it is not currently possible to use this method when  $s$  is a small ball containing any of  $0, 1, 2, \dots$  (then the result becomes indeterminate).

The Hurwitz zeta method becomes inefficient when  $|z| \rightarrow 0$  (it gives an indeterminate result when  $z = 0$ ). This is not a problem since we just use the defining series for the polylogarithm in that region. It also becomes inefficient when  $|z| \rightarrow \infty$ , for which an asymptotic expansion would better.

## 10.6 Algorithms for hypergeometric functions

The algorithms used to compute hypergeometric functions are described in [Joh2016]. Here, we state the most important error bounds.

### 10.6.1 Convergent series

Let

$$T(k) = \frac{\prod_{i=0}^{p-1} (a_i)_k}{\prod_{i=0}^{q-1} (b_i)_k} z^k.$$

We compute a factor  $C$  such that

$$\left| \sum_{k=n}^{\infty} T(k) \right| \leq C |T(n)|.$$

We check that  $\operatorname{Re}(b + n) > 0$  for all lower parameters  $b$ . If this does not hold,  $C$  is set to infinity. Otherwise, we cancel out pairs of parameters  $a$  and  $b$  against each other. We have

$$\left| \frac{a+k}{b+k} \right| = \left| 1 + \frac{a-b}{b+k} \right| \leq 1 + \frac{|a-b|}{|b+n|}$$

and

$$\left| \frac{1}{b+k} \right| \leq \frac{1}{|b+n|}$$

for all  $k \geq n$ . This gives us a constant  $D$  such that  $T(k+1) \leq DT(k)$  for all  $k \geq n$ . If  $D \geq 1$ , we set  $C$  to infinity. Otherwise, we take  $C = \sum_{k=0}^{\infty} D^k = (1-D)^{-1}$ .

### 10.6.2 Convergent series of power series

The same principle is used to get tail bounds for with  $a_i, b_i, z \in \mathbb{C}[[x]]$ , or more precisely, bounds for each coefficient in  $\sum_{k=N}^{\infty} T(k) \in \mathbb{C}[[x]]/\langle x^n \rangle$  given  $a_i, b_i, z \in \mathbb{C}[[x]]/\langle x^n \rangle$ . First, we fix some notation, assuming that  $A$  and  $B$  are power series:

- $A_{[k]}$  denotes the coefficient of  $x^k$  in  $A$ , and  $A_{[m:n]}$  denotes the power series  $\sum_{k=m}^{n-1} A_{[k]} x^k$ .
- $|A|$  denotes  $\sum_{k=0}^{\infty} |A_{[k]}| x^k$  (this can be viewed as an element of  $\mathbb{R}_{\geq 0}[[x]]$ ).
- $A \leq B$  signifies that  $|A|_{[k]} \leq |B|_{[k]}$  holds for all  $k$ .
- We define  $\mathcal{R}(B) = |B_{[0]}| - |B_{[1:\infty]}|$ .

Using the formulas

$$(AB)_{[k]} = \sum_{j=0}^k A_{[j]} B_{[k-j]}, \quad (1/B)_{[k]} = \frac{1}{B_{[0]}} \sum_{j=1}^k -B_{[j]} (1/B)_{[k-j]},$$

it is easy to prove the following bounds for the coefficients of sums, products and quotients of formal power series:

$$|A+B| \leq |A| + |B|, \quad |AB| \leq |A||B|, \quad |A/B| \leq |A|/\mathcal{R}(B).$$

If  $p \leq q$  and  $\operatorname{Re}(b_{i[0]} + N) > 0$  for all  $b_i$ , then we may take

$$D = |z| \prod_{i=1}^p \left( 1 + \frac{|a_i - b_i|}{\mathcal{R}(b_i + N)} \right) \prod_{i=p+1}^q \frac{1}{\mathcal{R}(b_i + N)}.$$

If  $D_{[0]} < 1$ , then  $(1-D)^{-1}|T(n)|$  gives the error bound.

Note when adding and multiplying power series with (complex) interval coefficients, we can use point-valued upper bounds for the absolute values instead of performing interval arithmetic throughout. For  $\mathcal{R}(B)$ , we must then pick a lower bound for  $|B_{[0]}|$  and upper bounds for the coefficients of  $|B_{[1:\infty]}|$ .

### 10.6.3 Asymptotic series for the confluent hypergeometric function

Let  $U(a, b, z)$  denote the confluent hypergeometric function of the second kind with the principal branch cut, and let  $U^* = z^a U(a, b, z)$ . For all  $z \neq 0$  and  $b \notin \mathbb{Z}$  (but valid for all  $b$  as a limit), we have (DLMF 13.2.42)

$$U(a, b, z) = \frac{\Gamma(1-b)}{\Gamma(a-b+1)} M(a, b, z) + \frac{\Gamma(b-1)}{\Gamma(a)} z^{1-b} M(a-b+1, 2-b, z).$$

Moreover, for all  $z \neq 0$  we have

$$\frac{{}_1F_1(a, b, z)}{\Gamma(b)} = \frac{(-z)^{-a}}{\Gamma(b-a)} U^*(a, b, z) + \frac{z^{a-b} e^z}{\Gamma(a)} U^*(b-a, b, -z)$$

which is equivalent to DLMF 13.2.41 (but simpler in form).

We have the asymptotic expansion

$$U^*(a, b, z) \sim {}_2F_0(a, a-b+1, -1/z)$$

where  ${}_2F_0(a, b, z)$  denotes a formal hypergeometric series, i.e.

$$U^*(a, b, z) = \sum_{k=0}^{n-1} \frac{(a)_k (a-b+1)_k}{k! (-z)^k} + \varepsilon_n(z).$$

The error term  $\varepsilon_n(z)$  is bounded according to DLMF 13.7. A case distinction is made depending on whether  $z$  lies in one of three regions which we index by  $R$ . Our formula for the error bound increases with the value of  $R$ , so we can always choose the larger out of two indices if  $z$  lies in the union of two regions.

Let  $r = |b - 2a|$ . If  $\operatorname{Re}(z) \geq r$ , set  $R = 1$ . Otherwise, if  $\operatorname{Im}(z) \geq r$  or  $\operatorname{Re}(z) \geq 0 \wedge |z| \geq r$ , set  $R = 2$ . Otherwise, if  $|z| \geq 2r$ , set  $R = 3$ . Otherwise, the bound is infinite. If the bound is finite, we have

$$|\varepsilon_n(z)| \leq 2\alpha C_n \left| \frac{(a)_n (a-b+1)_n}{n! z^n} \right| \exp(2\alpha \rho C_1 / |z|)$$

in terms of the following auxiliary quantities

$$\begin{aligned} \sigma &= |(b-2a)/z| \\ C_n &= \begin{cases} 1 & \text{if } R = 1 \\ \chi(n) & \text{if } R = 2 \\ (\chi(n) + \sigma \nu^2 n) \nu^n & \text{if } R = 3 \end{cases} \\ \nu &= \left( \frac{1}{2} + \frac{1}{2} \sqrt{1 - 4\sigma^2} \right)^{-1/2} \leq 1 + 2\sigma^2 \\ \chi(n) &= \sqrt{\pi} \Gamma(\tfrac{1}{2}n + 1) / \Gamma(\tfrac{1}{2}n + \tfrac{1}{2}) \\ \sigma' &= \begin{cases} \sigma & \text{if } R \neq 3 \\ \nu \sigma & \text{if } R = 3 \end{cases} \\ \alpha &= (1 - \sigma')^{-1} \\ \rho &= \tfrac{1}{2} |2a^2 - 2ab + b| + \sigma' (1 + \tfrac{1}{4} \sigma') (1 - \sigma')^{-2} \end{aligned}$$

### 10.6.4 Asymptotic series for Airy functions

Error bounds are based on Olver (DLMF section 9.7). For  $\arg(z) < \pi$  and  $\zeta = (2/3)z^{3/2}$ , we have

$$\begin{aligned} \text{Ai}(z) &= \frac{e^{-\zeta}}{2\sqrt{\pi}z^{1/4}} [S_n(\zeta) + R_n(z)], \quad \text{Ai}'(z) = -\frac{z^{1/4}e^{-\zeta}}{2\sqrt{\pi}} [(S'_n(\zeta) + R'_n(z))] \\ S_n(\zeta) &= \sum_{k=0}^{n-1} (-1)^k \frac{u(k)}{\zeta^k}, \quad S'_n(\zeta) = \sum_{k=0}^{n-1} (-1)^k \frac{v(k)}{\zeta^k} \\ u(k) &= \frac{(1/6)_k (5/6)_k}{2^k k!}, \quad v(k) = \frac{6k+1}{1-6k} u(k). \end{aligned}$$

Assuming that  $n$  is positive, the error terms are bounded by

$$|R_n(z)| \leq C|u(n)||\zeta|^{-n}, \quad |R'_n(z)| \leq C|v(n)||\zeta|^{-n}$$

where

$$C = \begin{cases} 2 \exp(7/(36|\zeta|)) & |\arg(z)| \leq \pi/3 \\ 2\chi(n) \exp(7\pi/(72|\zeta|)) & \pi/3 \leq |\arg(z)| \leq 2\pi/3 \\ 4\chi(n) \exp(7\pi/(36|\text{re}(\zeta)|)) |\cos(\arg(\zeta))|^{-n} & 2\pi/3 \leq |\arg(z)| < \pi. \end{cases}$$

For computing Bi when  $z$  is roughly in the positive half-plane, we use the connection formulas

$$\begin{aligned} \text{Bi}(z) &= -i(2w^{+1} \text{Ai}(zw^{-2}) - \text{Ai}(z)) \\ \text{Bi}(z) &= +i(2w^{-1} \text{Ai}(zw^{+2}) - \text{Ai}(z)) \end{aligned}$$

where  $w = \exp(\pi i/3)$ . Combining roots of unity gives

$$\begin{aligned} \text{Bi}(z) &= \frac{1}{2\sqrt{\pi}z^{1/4}} [2X + iY] \\ \text{Bi}(z) &= \frac{1}{2\sqrt{\pi}z^{1/4}} [2X - iY] \\ X &= \exp(+\zeta)[S_n(-\zeta) + R_n(zw^{\mp 2})], \quad Y = \exp(-\zeta)[S_n(\zeta) + R_n(z)] \end{aligned}$$

where the upper formula is valid for  $-\pi/3 < \arg(z) < \pi$  and the lower formula is valid for  $-\pi < \arg(z) < \pi/3$ . We proceed analogously for the derivative of Bi.

In the negative half-plane, we use the connection formulas

$$\begin{aligned} \text{Ai}(z) &= e^{+\pi i/3} \text{Ai}(z_1) + e^{-\pi i/3} \text{Ai}(z_2) \\ \text{Bi}(z) &= e^{-\pi i/6} \text{Ai}(z_1) + e^{+\pi i/6} \text{Ai}(z_2) \end{aligned}$$

where  $z_1 = -ze^{+\pi i/3}$ ,  $z_2 = -ze^{-\pi i/3}$ . Provided that  $|\arg(-z)| < 2\pi/3$ , we have  $|\arg(z_1)|, |\arg(z_2)| < \pi$ , and thus the asymptotic expansion for Ai can be used. As before, we collect roots of unity to obtain

$$\begin{aligned} \text{Ai}(z) &= A_1[S_n(i\zeta) + R_n(z_1)] + A_2[S_n(-i\zeta) + R_n(z_2)] \\ \text{Bi}(z) &= A_3[S_n(i\zeta) + R_n(z_1)] + A_4[S_n(-i\zeta) + R_n(z_2)] \end{aligned}$$

where  $\zeta = (2/3)(-z)^{3/2}$  and

$$A_1 = \frac{\exp(-i(\zeta - \pi/4))}{2\sqrt{\pi}(-z)^{1/4}}, \quad A_2 = \frac{\exp(+i(\zeta - \pi/4))}{2\sqrt{\pi}(-z)^{1/4}}, \quad A_3 = -iA_1, \quad A_4 = +iA_2.$$

The differentiated formulas are analogous.

### 10.6.5 Corner case of the Gauss hypergeometric function

In the corner case where  $z$  is near  $\exp(\pm\pi i/3)$ , none of the linear fractional transformations is effective. In this case, we use Taylor series to analytically continue the solution of the hypergeometric differential equation from the origin. The function  $f(z) = {}_2F_1(a, b, c, z_0 + z)$  satisfies

$$f''(z) = -\frac{((z_0 + z)(a + b + 1) - c)}{(z_0 + z)(z_0 - 1 + z)}f'(z) - \frac{ab}{(z_0 + z)(z_0 - 1 + z)}f(z).$$

Knowing  $f(0), f'(0)$ , we can compute the consecutive derivatives recursively, and evaluating the truncated Taylor series allows us to compute  $f(z), f'(z)$  to high accuracy for sufficiently small  $z$ . Some experimentation showed that two continuation steps

$$0 \rightarrow 0.375 \pm 0.625i \rightarrow 0.5 \pm 0.8125i \rightarrow z$$

gives good performance. Error bounds for the truncated Taylor series are obtained using the Cauchy-Kovalevskaya majorant method, following the outline in [Hoe2001]. The differential equation is majorized by

$$g''(z) = \frac{N+1}{2} \left( \frac{\nu}{1-\nu z} \right) g'(z) + \frac{(N+1)N}{2} \left( \frac{\nu}{1-\nu z} \right)^2 g(z)$$

provided that  $N$  and  $\nu \geq \max(1/|z_0|, 1/|z_0 - 1|)$  are chosen sufficiently large. It follows that we can compute explicit numbers  $A, N, \nu$  such that the simple solution  $g(z) = A(1 - \nu z)^{-N}$  of the differential equation provides the bound

$$|f_{[k]}| \leq g_{[k]} = A \binom{N+k}{k} \nu^k.$$

## 10.7 Algorithms for the arithmetic-geometric mean

With complex variables, it is convenient to work with the univariate function  $M(z) = \text{agm}(1, z)$ . The general case is given by  $\text{agm}(a, b) = aM(1, b/a)$ .

### 10.7.1 Functional equation

If the real part of  $z$  initially is not completely nonnegative, we apply the functional equation  $M(z) = (z+1)M(u)/2$  where  $u = \sqrt{z}/(z+1)$ .

Note that  $u$  has nonnegative real part, absent rounding error. It is not a problem for correctness if rounding makes the interval contain negative points, as this just inflates the final result.

For the derivative, the functional equation becomes  $M'(z) = [M(u) - (z-1)M'(u)/((1+z)\sqrt{z})]/2$ .

### 10.7.2 AGM iteration

Once  $z$  is in the right half plane, we can apply the AGM iteration ( $2a_{n+1} = a_n + b_n, b_{n+1}^2 = a_n b_n$ ) directly. The correct square root is given by  $\sqrt{a}\sqrt{b}$ , which is computed as  $\sqrt{ab}, i\sqrt{-ab}, -i\sqrt{-ab}, \sqrt{a}\sqrt{b}$  respectively if both  $a$  and  $b$  have positive real part, nonnegative imaginary part, nonpositive imaginary part, or otherwise.

It is shown in [Dup2006], p. 87 that, for  $z$  with nonnegative real part,  $|M(z) - a_n| \leq |a_n - b_n|$ .

A small improvement would be to switch to a series expansion for the last one or two steps.

### 10.7.3 First derivative

Assuming that  $z$  is exact and that  $|\arg(z)| \leq 3\pi/4$ , we compute  $(M(z), M'(z))$  simultaneously using a finite difference.

The basic inequality we need is  $|M(z)| \leq \max(1, |z|)$ , which is an immediate consequence of the AGM iteration.

By Cauchy's integral formula,  $|M^{(k)}(z)/k!| \leq CD^k$  where  $C = \max(1, |z| + r)$  and  $D = 1/r$ , for any  $0 < r < |z|$  (we choose  $r$  to be of the order  $|z|/4$ ). Taylor expansion now gives

$$\left| \frac{M(z+h) - M(z)}{h} - M'(z) \right| \leq \frac{CD^2h}{1-Dh}$$

assuming that  $h$  is chosen so that it satisfies  $hD < 1$ .

The forward finite difference requires two function evaluations at doubled precision. It would be more efficient to use a central difference (this could be implemented in the future).

When  $z$  is not exact, we evaluate at the midpoint as above and bound the propagated error using derivatives. Again by Cauchy's integral formula, we have

$$\begin{aligned} |M'(z + \varepsilon)| &\leq \frac{\max(1, |z| + |\varepsilon| + r)}{r} \\ |M''(z + \varepsilon)| &\leq \frac{2\max(1, |z| + |\varepsilon| + r)}{r^2} \end{aligned}$$

assuming that the circle centered on  $z$  with radius  $|\varepsilon| + r$  does not cross the negative half axis. We choose  $r$  of order  $|z|/2$  and verify that all assumptions hold.

### 10.7.4 Higher derivatives

The function  $W(z) = 1/M(z)$  is D-finite. The coefficients of  $W(z+x) = \sum_{k=0}^{\infty} c_k x^k$  satisfy

$$-2z(z^2 - 1)c_2 = (3z^2 - 1)c_1 + zc_0,$$

$$-(k+2)(k+3)z(z^2 - 1)c_{k+3} = (k+2)^2(3z^2 - 1)c_{k+2} + (3k(k+3) + 7)zc_{k+1} + (k+1)^2c_k$$

in general, and

$$-(k+2)^2c_{k+2} = (3k(k+3) + 7)c_{k+1} + (k+1)^2c_k$$

when  $z = 1$ .

## HISTORY, CREDITS AND REFERENCES

### 11.1 Credits and references

#### 11.1.1 License

Arb is free software; you can redistribute it and/or modify it under the terms of the GNU Lesser General Public License (LGPL) as published by the Free Software Foundation; either version 2.1 of the License, or (at your option) any later version.

Arb is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See the GNU Lesser General Public License for more details.

You should have received a copy of the GNU Lesser General Public License along with Arb (see the LICENSE file in the root of the Arb source directory). If not, see <http://www.gnu.org/licenses/>.

Versions of Arb up to and including 2.8 were distributed under the GNU General Public License (GPL), not the LGPL. The switch to the LGPL applies retroactively; i.e. users may redistribute older versions of Arb under the LGPL if they prefer.

#### 11.1.2 Authors

Fredrik Johansson is the main author. The project was started in 2012 as a numerical extension of FLINT, and the initial design was heavily based on FLINT 2.0 (with particular credit to Bill Hart and Sebastian Pancratz).

The following authors have developed major new features.

- Pascal Molin - Dirichlet characters, Dirichlet L-functions, discrete logarithm computation
- Alex Griffing - sinc function, matrix trace, improved matrix squaring, boolean matrices, improved structured matrix exponentials, Cholesky decomposition, miscellaneous patches

Several people have contributed patches, bug reports, or substantial feedback. This list (ordered by time of first contribution) is probably incomplete.

- Bill Hart - build system, Windows 64 support, design of FLINT
- Sebastian Pancratz - divide-and-conquer polynomial composition algorithm (taken from FLINT)
- The MPFR development team - Arb includes two-limb multiplication code taken from MPFR
- Jonathan Bober - original code for Dirichlet characters, C++ compatibility fixes
- Yuri Matiyasevich - feedback about the zeta function and root-finding code
- Abhinav Baid - dot product and norm functions
- Ondřej Čertík - bug reports, feedback
- Andrew Booker - bug reports, feedback

- Francesco Biscani - C++ compatibility fixes, feedback
- Clemens Heuberger - work on Arb interface in Sage, feedback
- Marc Mezzarobba - work on Arb interface in Sage, bug reports, feedback
- Ricky Farr - convenience functions, feedback
- Marcello Seri - fix for static builds on OS X
- Tommy Hofmann - matrix transpose, comparison, other utility methods, Julia interface
- Alexander Kobel - documentation and code cleanup patches
- Hrvoje Abraham - patches for MinGW compatibility
- Julien Puydt - soname versioning support
- Jeroen Demeyer - patch for major bug on PPC64
- Isuru Fernando - continuous integration setup, support for cmake and MSVC builds
- François Bissey - build system patches

### 11.1.3 Funding

From 2012 to July 2014, Fredrik's work on Arb was supported by Austrian Science Fund FWF Grant Y464-N18 (Fast Computer Algebra for Special Functions). During that period, he was a PhD student (and briefly a postdoc) at RISC, Johannes Kepler University, Linz, supervised by Manuel Kauers.

From September 2014 to October 2015, Fredrik was a postdoc at INRIA Bordeaux and Institut de Mathématiques de Bordeaux, in the LFANT project-team headed by Andreas Enge. During that period, Fredrik's work on Arb was supported by ERC Starting Grant ANTICS 278537 (Algorithmic Number Theory in Computer Science) [http://cordis.europa.eu/project/rcn/101288\\_en.html](http://cordis.europa.eu/project/rcn/101288_en.html) Since October 2015, Fredrik is a CR2 researcher in the LFANT team, funded by INRIA.

### 11.1.4 Software

The following software has been helpful in the development of Arb.

- GMP (Torbjörn Granlund and others), <http://gmplib.org>
- MPPIR (Brian Gladman, Jason Moxham, William Hart and others), <http://mpir.org>
- MPFR (Guillaume Hanrot, Vincent Lefèvre, Patrick Pélissier, Philippe Théveny, Paul Zimmermann and others), <http://mpfr.org>
- FLINT (William Hart, Sebastian Pancratz, Andy Novocin, Fredrik Johansson, David Harvey and others), <http://flintlib.org>
- Sage (William Stein and others), <http://sagemath.org>
- Pari/GP (The Pari group), <http://pari.math.u-bordeaux.fr/>
- SymPy (Ondřej Čertík, Aaron Meurer and others), <http://sympy.org>
- mpmath (Fredrik Johansson and others), <http://mpmath.org>
- Mathematica (Wolfram Research), <http://www.wolfram.com/mathematica>
- HolonomicFunctions (Christoph Koutschan), <http://www.risc.jku.at/research/combinat/software/HolonomicFunctions/>
- Sphinx (George Brandl and others), <http://sphinx.pocoo.org>
- CM (Andreas Enge), <http://www.multiprecision.org/index.php?prog=cm>
- ore\_algebra (Manuel Kauers, Maximilian Jaroschek, Fredrik Johansson), [http://www.risc.jku.at/research/combinat/software/ore\\_algebra/](http://www.risc.jku.at/research/combinat/software/ore_algebra/)

### 11.1.5 Citing Arb

To cite Arb in a scientific paper, the following reference can be used:

F. Johansson. “Arb: efficient arbitrary-precision midpoint-radius interval arithmetic”, *IEEE Transactions on Computers*, 66(8):1281-1292, 2017. DOI: [10.1109/TC.2017.2690633](https://doi.org/10.1109/TC.2017.2690633).

In BibTeX format:

```
@article{Johansson2017arb,
  author = {F. Johansson},
  title = {Arb: efficient arbitrary-precision midpoint-radius interval arithmetic},
  journal = {IEEE Transactions on Computers},
  year = {2017},
  volume = {66},
  issue = {8},
  pages = {1281--1292},
  doi = {10.1109/TC.2017.2690633},
}
```

Alternatively, the Arb manual or website can be cited directly.

The *IEEE Transactions on Computers* paper supersedes the following extended abstract, which is now outdated:

F. Johansson. “Arb: a C library for ball arithmetic”, *ACM Communications in Computer Algebra*, 47(4):166-169, 2013.

### 11.1.6 Bibliography

(In the PDF edition, this section is empty. See the bibliography listing at the end of the document.)

## 11.2 History and changes

For more details, view the commit log in the git repository <https://github.com/fredrik-johansson/arb>

Old releases of the code can be accessed from <https://github.com/fredrik-johansson/arb/releases>

### 11.2.1 Old versions of the documentation

- <http://arblib.org/arb-2.3.0.pdf>

### 11.2.2 2017-07-10 - version 2.11.1

- Avoid use of a function that was unavailable in the latest public FLINT release

### 11.2.3 2017-07-09 - version 2.11.0

- Special functions
  - Added the Lambert W function (`arb_lambertw`, `acb_lambertw`, `arb_poly_lambertw_series`, `acb_poly_lambertw_series`). All complex branches and evaluation of derivatives are supported.
  - Added the `acb_expm1` method, complementing `arb_expm1`.
  - Added `arb_sinc_pi`, `acb_sinc_pi`.
  - Optimized handling of more special cases in the Hurwitz zeta function.
- Polynomials
  - Added the `arb_fmpz_poly` module to provide Arb methods for FLINT integer polynomials.
  - Added methods for evaluating an `fmpz_poly` at `arb_t` and `acb_t` arguments.
  - Added `arb_fmpz_poly_complex_roots` for computing the real and complex roots of an integer polynomial, turning the functionality previously available in the `poly_roots.c` example program into a proper library function.
  - Added a method (`arb_fmpz_poly_gauss_period_minpoly`) for constructing minimal polynomials of Gaussian periods.
  - Added `arb_poly_product_roots_complex` for constructing a real polynomial from complex conjugate roots.
- Miscellaneous
  - Fixed test code in the `dirichlet` module for 32-bit systems (contributed by Pascal Molin).
  - Use `flint_abort()` instead of `abort()` (contributed by Tommy Hofmann).
  - Fixed the static library install path (contributed by François Bissey).
  - Made `arb_nonnegative_part()` a publicly documented method.
  - Arb now requires FLINT version 2.5 or later.

### 11.2.4 2017-02-27 - version 2.10.0

- General
  - Changed a large number of methods from inline functions to normal functions, substantially reducing the size of the built library.
  - Fixed a few minor memory leaks (missing `clear()` calls).
- Basic arithmetic
  - Added `arb_is_int_2exp_si` and `acb_is_int_2exp_si`.
  - Added `arf_sosq` for computing  $x^2+y^2$  of floating-point numbers.
  - Improved error bounds for complex square roots in the left half plane.
  - Improved error bounds for complex reciprocal (`acb_inv`) and division.
  - Added the internal helper `mag_get_d_log2_approx` as a public method.
- Elliptic functions and integrals

- New module `acb_elliptic.h` for elliptic functions and integrals.
- Added complete elliptic integral of the third kind.
- Added Legendre incomplete elliptic integrals (first, second, third kinds).
- Added Carlson symmetric incomplete elliptic integrals (RF, RC, RG, RJ, RD).
- Added Weierstrass elliptic zeta and sigma functions.
- Added inverse Weierstrass elliptic p-function.
- Added utility functions for computing the Weierstrass invariants and lattice roots.
- Improved computation of derivatives of Jacobi theta functions by using modular transformations, and added a main evaluation function (`acb_modular_theta_jet`).
- Improved detection of pure real or pure imaginary parts in various cases of evaluating theta and modular functions.
- Other special functions
  - New, far more efficient implementation of the dilogarithm function (`acb_polylog` with  $s = 2$ ).
  - Fixed an issue in the Hurwitz zeta function leading to unreasonable slowdown for certain complex input.
  - Added `add_acb_poly_exp_pi_i_series`.
  - Added `arb_poly_log1p_series`, `acb_poly_log1p_series`.

### 11.2.5 2016-12-02 - version 2.9.0

- License
  - Changed license from GPL to LGPL.
- Build system and compatibility
  - Fixed FLINT includes to use `flint/foo.h` instead of `foo.h`, simplifying compilation on many systems.
  - Added another alias for the dynamic library to fix make check on certain systems (contributed by Andreas Enge).
  - Travis CI support (contributed by Isuru Fernando).
  - Added support for `ARB_TEST_MULTIPLIER` environment variable to control the number of test iterations.
  - Support building with CMake (contributed by Isuru Fernando).
  - Support building with MSVC on Windows (contributed by Isuru Fernando).
  - Fixed unsafe use of `FLINT_ABS` for `slong`  $\rightarrow$  `ulong` conversion in `arf.h`, which caused failures on MIPS and ARM systems.
- Basic arithmetic and methods
  - Fixed `mag_addmul(x,x,x)` with `x` having a mantissa of all ones. This could produce a non-normalized `mag_t` value, potentially leading to incorrect results in arb and acb level arithmetic. This bug was caught by new test code, and fortunately would have been hard to trigger accidentally.
  - Added fasth paths for error bound calculations in `arb_sqrt` and `arb_div`, speeding up these operations significantly at low precision
  - Added support for round-to-nearest in all arf methods.
  - Added `fprint` methods (contributed by Alex Griffing).

- Added `acb_printn` and `acb_fprintn` methods to match `arb_printn`.
  - Added `arb_equal_si` and `acb_equal_si`.
  - Added `arb_can_round_mpf`.
  - Added `arb_get_ubound_arf`, `arb_get_lbound_arf` (contributed by Tommy Hofmann).
  - Added `sign` function (`arb_sgn`).
  - Added complex sign functions (`acb_sgn`, `acb_csgn`).
  - Rewrote `arb_contains_fmpq` to make the test exact.
  - Optimized `mag_get_fmpq`.
  - Optimized `arf_get_fmpz` and added more robust test code.
  - Rewrote `arb_get_unique_fmpz` and `arb_get_interval_fmpz_2exp`, reducing overhead, making them more robust with huge exponents, and documenting their behavior more carefully.
  - Optimized `arb_union`.
  - Optimized `arf_is_int`, `arf_is_int_2exp_si` and changed these from inline to normal functions.
  - Added `mag_const_pi`, `mag_sub`, `mag_expinv`.
  - Optimized binary-to-decimal conversion for huge exponents by using exponential function instead of binary powering.
  - Added `arb_intersection` (contributed by Alex Griffing).
  - Added `arb_min`, `arb_max` (contributed by Alex Griffing).
  - Fixed a bug in `arb_log` and in test code on 64-bit Windows due to unsafe use of MPFR which only uses 32-bit exponents on Win64.
  - Improved some test functions to reduce the chance of reporting spurious failures.
  - Added squaring functions (`arb_sqr`, `acb_sqr`) (contributed by Ricky Farr).
  - Added `arf_frexp`.
  - Added `arf_cmp_si`, `arf_cmp_ui`, `arf_cmp_d`.
  - Added methods to count allocated bytes (`arb_allocated_bytes`, `_arb_vec_allocated_bytes`, etc.).
  - Added methods to predict memory usage for large vectors (`_arb/_acb_vec_estimate_allocated_bytes`).
  - Changed `clear()` methods from inline to normal functions, giving 8% faster compilation and 25% smaller `libarb.so`.
  - Added `acb_unit_root` and `_acb_vec_unit_roots` (contributed by Pascal Molin).
- Polynomials
    - Added `sinh` and `cosh` functions of power series (`arb/acb_poly_sinh/cosh_series` and `sinh_cosh_series`).
    - Use basecase series inversion algorithm to improve speed and error bounds in `arb/acb_poly_inv_series`.
    - Added functions for fast polynomial Taylor shift (`arb_poly_taylor_shift`, `acb_poly_taylor_shift` and variants).
    - Fast handling of special cases in polynomial composition.
    - Added `acb_poly` scalar `mul` and `div` convenience methods (contributed by Alex Griffing).
    - Added `set_trunc`, `set_trunc_round` convenience methods.
    - Added `add_series`, `sub_series` methods for truncating addition.

- Added polynomial `is_zero`, `is_one`, `is_x`, valuation convenience methods.
- Added hack to `arb_poly_mullo` and `acb_poly_mullo` to avoid overhead when doing an in-place multiplication with length at most 2.
- Added binomial and Borel transform methods for `acb_poly`.
- Matrices
  - Added Cholesky decomposition plus solving and inverse for positive definite matrices (`arb_mat_cho`, `arb_mat_spd_solve`, `arb_mat_spd_inv` and related methods) (contributed by Alex Griffing).
  - Added LDL decomposition and inverse and solving based on LDL decomposition for real matrices (`arb_mat_ldl`, `arb_mat_solve_ldl_precomp`, `arb_mat_inv_ldl_precomp`) (contributed by Alex Griffing).
  - Improved the entrywise error bounds in matrix exponential computation to preserve sparsity and give exact entries where possible in many cases (contributed by Alex Griffing).
  - Added public functions for computing the truncated matrix exponential Taylor series (`arb_mat_exp_taylor_sum`, `acb_mat_exp_taylor_sum`).
  - Added functions related to sparsity structure (`arb_mat_entrywise_is_zero`, `arb_mat_count_is_zero`, etc.) (contributed by Alex Griffing).
  - Entrywise multiplication (`arb_mat_mul_entrywise`, `acb_mat_mul_entrywise`) (contributed by Alex Griffing).
  - Added `is_empty` and `is_square` convenience methods (contributed by Alex Griffing).
  - Added the `bool_mat` helper module for matrices over the boolean semiring (contributed by Alex Griffing).
  - Added Frobenius norm computation (contributed by Alex Griffing).
- Miscellaneous special functions
  - Added evaluation of Bernoulli polynomials (`arb_bernoulli_poly_ui`, `acb_bernoulli_poly_ui`).
  - Added convenience function for evaluation of huge Bernoulli numbers (`arb_bernoulli_fmpz`).
  - Added Euler numbers (`arb_euler_number_ui`, `arb_euler_number_fmpz`).
  - Added fast approximate partition function (`arb_partitions_fmpz/ui`).
  - Optimized partition function for  $n < 1000$  by using recurrence for the low 64 bits.
  - Improved the worst-case error bound in `arb_atan`.
  - Added `arb_log_base_ui`.
  - Added complex sinc function (`acb_sinc`).
  - Special handling of  $z = 1$  when computing polylogarithms.
  - Fixed `agm(-1,-1)` to output 0 instead of indeterminate.
  - Made working precision in `arb_gamma` and `acb_gamma` more sensitive to the input accuracy.
- Hypergeometric functions
  - Compute `erf` and `erfc` without cancellation problems for large or complex  $z$ .
  - Avoid re-computing the square root of  $\pi$  in several places.
  - Added generalized hypergeometric function (`acb_hypgeom_pfq`).
  - Implement binary splitting and rectangular splitting for evaluation of hypergeometric series with a power series parameter, greatly speeding up `Y_n`, `K_n` and other functions at high precision, as well as speeding up high-order parameter derivatives.

- Use binary splitting more aggressively in `acb_hypgeom_pfq_sum` to reduce error bound inflation.
- Asymptotic expansions of hypergeometric functions: more accurate parameter selection, and better handling of terminating cases.
- Tweaked algorithm selection and working precision in `acb_hypgeom_m`.
- Avoid dividing by the denominator of the next term in `acb_hypgeom_sum`, which would lead to a division by zero when evaluating hypergeometric polynomials.
- Fixed a bug in hypergeometric series evaluation resulting in near-integers not being skipped in some cases, leading to unnecessary loss of precision.
- Added series expansions of Airy functions (`acb_hypgeom_airy_series`, `acb_hypgeom_airy_jet`).
- Fixed a case where Airy functions accidentally chose the worst algorithm instead of the best one.
- Added functions for computing `erf`, `erfc`, `erfi` of power series in the `acb_hypgeom` module.
- Added series expansion of the logarithmic integral (`acb_hypgeom_li_series`).
- Added Fresnel integrals (`acb_hypgeom_fresnel`, `acb_hypgeom_fresnel_series`).
- Added the lower incomplete gamma function (`acb_hypgeom_gamma_lower`) (contributed by Alex Griffing).
- Added series expansion of the lower incomplete gamma function (`acb_hypgeom_gamma_lower_series`) (contributed by Alex Griffing).
- Added support for computing the regularized incomplete gamma functions.
- Use slightly sharper error bound for analytic continuation of `2F1`.
- Added support for computing finite limits of `2F1` with inexact parameters differing by integers.
- Added the incomplete beta function (`acb_hypgeom_beta_lower`, `acb_hypgeom_beta_lower_series`).
- Improved `acb_hypgeom_u` to use a division-avoiding algorithm for small polynomial cases.
- Added `arb_hypgeom` module, wrapping the complex hypergeometric functions for more convenient use with the `arb_t` type.
- Dirichlet L-functions and Riemann zeta function
  - New module `dirichlet` for working algebraically with Dirichlet groups and characters (contributed by Pascal Molin).
  - New module `acb_dirichlet` for numerical evaluation of Dirichlet characters and L-functions (contributed by Pascal Molin).
  - Efficient representation and manipulation of Dirichlet characters using the Conrey representation (contributed by Pascal Molin).
  - New module `dlog` for word-size discrete logarithm evaluation, used to support algorithms on Dirichlet characters (contributed by Pascal Molin).
  - Methods for properties, evaluation, iteration, pairing, lift, lowering etc. of Dirichlet characters (contributed by Pascal Molin).
  - Added `acb_dirichlet_roots` methods for fast evaluation of many roots of unity (contributed by Pascal Molin).
  - Added `acb_dirichlet_hurwitz_precomp` methods for fast multi-evaluation of the Hurwitz zeta function for many parameter values.
  - Added methods for computing Gauss, Jacobi and theta sums over Dirichlet characters (contributed by Pascal Molin).

- Added methods (`acb_dirichlet_l`, `acb_dirichlet_l_jet`, `acb_dirichlet_l_series`) for evaluation of Dirichlet L-functions and their derivatives.
- Implemented multiple algorithms for evaluation of Dirichlet L-functions depending on the argument (Hurwitz zeta function decomposition, Euler product, functional equation).
- Added methods (`acb_dirichlet_hardy_z`, `acb_dirichlet_hardy_z_series`, etc.) for computing the Hardy Z-function corresponding to a Dirichlet L-function.
- Added fast bound for Hurwitz zeta function (`mag_hurwitz_zeta_uiui`).
- Improved parameter selection in Hurwitz zeta function to target relative instead of absolute error for large positive  $s$ .
- Improved parameter selection in Hurwitz zeta function to avoid computing unnecessary Bernoulli numbers for large imaginary  $s$ .
- Added Dirichlet eta function (`acb_dirichlet_eta`).
- Implemented the Riemann-Siegel formula for faster evaluation of the Riemann zeta function at large height.
- Added smooth-index algorithm for the main sum when evaluating the Riemann zeta function, avoiding the high memory usage of the full sieving algorithm when the number of terms gets huge.
- Improved tuning for using the Euler product when computing the Riemann zeta function.
- Example programs
  - Added logistic map example program.
  - Added lvalue example program.
  - Improved `poly_roots` in several ways: identify roots that are exactly real, automatically perform squarefree factorization, use power hack, and allow specifying a product of polynomials as input on the command line.
- Housekeeping
  - New section in the documentation giving an introduction to ball arithmetic and using the library.
  - Tidied, documented and added test code for the `fmpz_extras` module.
  - Added proper documentation and test code for many helper methods.
  - Removed the obsolete `fmprrb` module entirely.
  - Documented more algorithms and formulas.
  - Clarified integer overflow issues and use of `ARF_PREC_EXACT` in the documentation.
  - Added `.gitignore` file.
  - Miscellaneous improvements to the documentation.

### 11.2.6 2015-12-31 - version 2.8.1

- Fixed 32-bit test failure for the Laguerre function.
- Made the Laguerre function indeterminate at negative integer orders, to be consistent with the test code.

### 11.2.7 2015-12-29 - version 2.8.0

- Compatibility and build system
  - Windows64 support (contributed by Bill Hart).
  - Fixed a bug that broke basic arithmetic on targets where FLINT uses fallback code instead of assembly code, such as PPC64 (contributed by Jeroen Demeyer).
  - Fixed configure to use EXTRA\_SHARED\_FLAGS/LDFLAGS, and other build system fixes (contributed by Tommy Hofmann, Bill Hart).
  - Added soname versioning (contributed by Julien Puydt).
  - Fixed test code on MinGW (contributed by Hrvoje Abraham).
  - Miscellaneous fixes to simplify interfacing Arb from Julia.
- Arithmetic and elementary functions
  - Fixed `arf_get_d` to handle underflow/overflow correctly and to support round-to-nearest.
  - Added more complex inverse hyperbolic functions (`acb_asin`, `acb_acos`, `acb_asinh`, `acb_acosh`, `acb_atanh`).
  - Added `arb_contains_int` and `acb_contains_int` for testing whether an interval contains any integer.
  - Added `acb_quadratic_roots_fmpz`.
  - Improved `arb_sinh` to use a more accurate formula for  $x < 0$ .
  - Added sinc function (`arb_sinc`) (contributed by Alex Griffing).
  - Fixed bug in `arb_exp` affecting convergence for huge input.
  - Faster implementation of `arb_div_2expm1_ui`.
  - Added `mag_root`, `mag_geom_series`.
  - Improved and added test code for `arb_add_error` functions.
  - Changed `arb_pow` and `acb_pow` to make  $\text{pow}(0, \text{positive}) = 0$  instead of nan.
  - Improved `acb_sqrt` to return finite output for finite input straddling the branch cut.
  - Improved `arb_set_interval_arf` so that  $[\text{inf}, \text{inf}] = \text{inf}$  instead of an infinite interval.
  - Added computation of Bell numbers (`arb_bell_fmpz`).
  - Added `arb_power_sum_vec` for computing power sums using Bernoulli numbers.
  - Added computation of the Fujiwara root bound for `acb_poly`.
  - Added code to identify all the real roots of a real polynomial (`acb_poly_validate_real_roots`).
  - Added several convenient assignment functions, including `arb_set_d`, `acb_set_d`, `acb_set_d_d`, `acb_set_fmpz_fmpz` (contributed by Ricky Farr).
  - Added many accessor functions (`_arb/acb_vec_entry_ptr`, `arb_get_mid/rad_arb`, `acb_real/imag_ptr`, `arb_mid/rad_ptr`, `acb_get_real/imag`).
  - Added missing functions `acb_add_si`, `acb_sub_si`.
  - Renamed `arb_root` to `arb_root_ui` (keeping alias) and added `acb_root_ui`.
- Special functions
  - Implemented the Gauss hypergeometric function  ${}_2F_1$  and its regularized version.
  - Fixed two bugs in `acb_hypgeom_pfq_series_direct` discovered while implementing  ${}_2F_1$ . In rare cases, these could lead to incorrect values for functions depending on parameter derivatives of hypergeometric series.

- \* The first bug involved incorrect handling of negative integer parameters. The bug only affected 2F1 and higher functions; it did not affect correctness of any previously implemented functions that relied on `acb_hypgeom_pfq_series_direct` (such as Bessel Y and K functions of integer order).
- \* The second bug involved a too small bound being computed for the sum of a geometric series. The geometric series bound is nearly tight for 2F1, and the incorrect version caused immediate test failures for that function. Theoretically, this bug affected correctness of some previously-implemented functions that relied on `acb_hypgeom_pfq_series_direct` (such as Bessel Y and K functions of integer order), but since the geometric bound is not as tight in those cases, those functions were still reliable in practice (no failing test case has been found).
- Implemented Airy functions and their derivatives (`acb_hypgeom_airy`).
- Implemented the confluent hypergeometric function 0F1 (`acb_hypgeom_0f1`).
- Implemented associated Legendre functions P and Q.
- Implemented Chebyshev, Jacobi, Gegenbauer, Laguerre, Hermite functions.
- Implemented spherical harmonics.
- Added function for computing Bessel J and Y functions simultaneously.
- Added rising factorials for non-integer  $n$  (`arb_rising`, `acb_rising`).
- Made rising factorials use gamma function for large integer  $n$ .
- Faster algorithm for theta constants and Dedekind eta function at very high precision.
- Fixed `erf` to give finite values instead of  $\pm\infty$  for big imaginary input.
- Improved `acb_zeta` (and `arb_zeta`) to automatically use fast code for integer zeta values.
- Added double factorial (`arb_doublefac_ui`).
- Added code for generating Hilbert class polynomials (`acb_modular_hilbert_class_poly`).
- Matrices
  - Added faster matrix squaring (`arb/acb_mat_sqr`) (contributed by Alex Griffing).
  - Added matrix trace (`arb/acb_mat_trace`) (contributed by Alex Griffing).
  - Added `arb/acb_mat_set_round_fmpz_mat`, `acb_mat_set(_round)_arb_mat` (contributed by Tommy Hofmann).
  - Added `arb/acb_mat_transpose` (contributed by Tommy Hofmann).
  - Added comparison methods `arb/acb_mat_eq/ne` (contributed by Tommy Hofmann).
- Other
  - Added `complex_plot` example program.
  - Added Airy functions to `real_roots` example program.
  - Other minor patches were contributed by Alexander Kobel, Marc Mezzarobba, Julien Puydt.
  - Removed obsolete file `config.h`.

### 11.2.8 2015-07-14 - version 2.7.0

- Hypergeometric functions
  - Implemented Bessel I and Y functions (`acb_hypgeom_bessel_i`, `acb_hypgeom_bessel_y`).
  - Fixed bug in Bessel K function giving the wrong branch for negative real arguments.
  - Added code for evaluating complex hypergeometric series binary splitting.

- Added code for evaluating complex hypergeometric series using fast multipoint evaluation.
- Gamma related functions
  - Implemented the Barnes G-function and its continuous logarithm (`acb_barnes_g`, `acb_log_barnes_g`).
  - Implemented the generalized polygamma function (`acb_polygamma`).
  - Implemented the reflection formula for the logarithmic gamma function (`acb_lgamma`, `acb_poly_lgamma_series`).
  - Implemented the digamma function of power series (`arb_poly_digamma_series`, `acb_poly_digamma_series`).
  - Improved `acb_poly_zeta_series` to produce exact zero imaginary parts in most cases when the result should be real-valued.
  - Made the real logarithmic gamma function (`arb_lgamma`, `arb_poly_lgamma_series`) abort more quickly for negative input.
- Elementary functions
  - Added `arb_exp_expinv` and `acb_exp_expinv` functions for simultaneously computing  $\exp(x)$ ,  $\exp(-x)$ .
  - Improved `acb_tan`, `acb_tan_pi`, `acb_cot` and `acb_cot_pi` for input with large imaginary parts.
  - Added complex hyperbolic functions (`acb_sinh`, `acb_cosh`, `acb_sinh_cosh`, `acb_tanh`, `acb_coth`).
  - Added `acb_log_sin_pi` for computing the logarithmic sine function without branch cuts away from the real line.
  - Added `arb_poly_cot_pi_series`, `acb_poly_cot_pi_series`.
  - Added `arf_root` and improved speed of `arb_root`.
  - Tuned algorithm selection in `arb_pow_fmpq`.
- Other
  - Added documentation for arb and acb vector functions.

### 11.2.9 2015-04-19 - version 2.6.0

- Special functions
  - Added the Bessel K function.
  - Added the confluent hypergeometric functions M and U.
  - Added exponential, trigonometric and logarithmic integrals `ei`, `si`, `shi`, `ci`, `chi`, `li`.
  - Added the complete elliptic integral of the second kind `E`.
  - Added support for computing hypergeometric functions with power series as parameters.
  - Fixed special cases in Bessel J function returning useless output.
  - Fixed precision of zeta function accidentally being capped at 7000 digits (bug in 2.5).
  - Special-cased real input in the gamma functions for complex types.
  - Fixed `exp` of huge numbers outputting unnecessarily useless intervals.
  - Fixed broken code in `erf` that sometimes gave useless output.
  - Made selection of number of terms in hypergeometric series more robust.
- Polynomials and power series.

- Added `sin_pi`, `cos_pi` and `sin_cos_pi` for real and complex power series.
- Speeded up series reciprocal and division for `length = 2`.
- Added `add_si` methods for polynomials.
- Made `inv_series` and `div_series` with zero input produce indeterminates instead of aborting.
- Added `arb_poly_majorant`, `acb_poly_majorant`.
- Basic functions
  - Added comparison methods `arb_eq`, `arb_ne`, `arb_lt`, `arb_le`, `arb_gt`, `arb_ge`, `acb_eq`, `acb_ne`.
  - Added `acb_rel_accuracy_bits` and improved the real version.
  - Fixed precision of constants like `pi` behaving more nondeterministically than necessary.
  - Fixed `arf_get_mag_lower(nan)` to output 0 instead of `inf`.
- Other
  - Removed call to `fmprq_dedekind_sum` which only exists in the git version of flint.
  - Fixed a test code bug that could cause crashes on some systems.
  - Added fix for static build on OS X (thanks Marcello Seri).
  - Miscellaneous corrections to the documentation.

### 11.2.10 2015-01-28 - version 2.5.0

- String conversion
  - Added `arb_set_str`.
  - Added `arb_get_str` and `arb_printn` for pretty-printed rigorous decimal output.
  - Added helper functions for binary to decimal conversion.
- Core arithmetic
  - Improved speed of division when using GMP instead of MPIR.
  - Improved complex division with a small denominator.
  - Removed a little bit of overhead for complex squaring.
- Special functions
  - Faster code for `atan` at very high precision, used instead of `mpfr_atan`.
  - Optimized elementary functions slightly for small input.
  - Added modified error functions `erfc` and `erfi`.
  - Added the generalized exponential integral.
  - Added the upper incomplete gamma function.
  - Implemented the complete elliptic integral of the first kind.
  - Implemented the arithmetic-geometric mean of complex numbers.
  - Optimized `arb_digamma` for small integers.
  - Made `mag_log_ui`, `mag_binpow_uiui` and `mag_polylog_tail` proper functions.
  - Added `pow`, `agm`, `erf`, `elliptic_k`, `elliptic_p` as functions of complex power series.
  - Added incomplete gamma function of complex power series.

- Improved code for bounding complex rising factorials (the old code could potentially have given wrong results in degenerate cases).
- Added `arb_sqrt1pm1`, `arb_atanh`, `arb_asinh`, `arb_atanh`.
- Added `arb_log1p`, `acb_log1p`, `acb_atan`.
- Added `arb_hurwitz_zeta`.
- Improved parameter selection in the Hurwitz zeta function to try to avoid stalling when given enormous input.
- Optimized `sqrt` and `rsqrt` of power series when given a binomial as input.
- Made `arb_bernoulli_ui(264-2)` not crash.
- Fixed `rgamma` of negative integers returning indeterminate.
- Polynomials and matrices
  - Added characteristic polynomial computation for real and complex matrices.
  - Added polynomial `set_round` methods.
  - Added `is_real` methods for more types.
  - Added more `get_unique_fmpz` methods.
  - Added code for generating Swinnerton-Dyer polynomials.
  - Improved error bounding in `det()` and `exp()` of complex matrices to recognize when the result is real-valued.
  - Changed polynomial `divrem` to return success/fail instead of aborting on divide by zero.
- Miscellaneous
  - Added logo to documentation.
  - Made inlined functions build as part of the library.
  - Silenced a clang warning.
  - Made `_acb_vec_sort_pretty` a library function.

### 11.2.11 2014-11-15 - version 2.4.0

- Arithmetic and core functions
  - Made evaluation of `sin`, `cos` and `exp` at medium precision faster using the `sqrt` trick.
  - Optimized `arb_sinh` and `arb_sinh_cosh`.
  - Optimized complex division with a small denominator.
  - Optimized cubing of complex numbers.
  - Added `floor` and `ceil` functions for the `arf` and `arb` types.
  - Added `acb_poly` powering functions.
  - Added `acb_exp_pi_i`.
  - Added functions for evaluation of Chebyshev polynomials.
  - Fixed `arb_div` to output `nan` for input containing `nan`.
- Added a module `acb_hypgeom` for hypergeometric functions
  - Evaluation of the generalized hypergeometric function in convergent cases.
  - Evaluation of confluent hypergeometric functions using asymptotic expansions.
  - The Bessel function of the first kind for complex input.

- The error function for complex input.
- Added a module `acb_modular` for modular forms and elliptic functions
  - Support for working with modular transformations.
  - Mapping a point to the fundamental domain.
  - Evaluation of Jacobi theta functions and their series expansions.
  - The Dedekind eta function.
  - The  $j$ -invariant and the modular lambda and delta function.
  - Eisenstein series.
  - The Weierstrass elliptic function and its series expansion.
- Miscellaneous
  - Fixed `mag_print` printing a too large exponent.
  - Fixed `printd` methods to use a fallback instead of aborting when printing numbers too large for MPFR.
  - Added version number string (`arb_version`).
  - Various additions to the documentation.

### 11.2.12 2014-09-25 - version 2.3.0

- Removed most of the legacy (Arb 1.x) modules.
- Updated build scripts, hopefully fixing various issues.
- New implementations of `arb_sin`, `arb_cos`, `arb_sin_cos`, `arb_atan`, `arb_log`, `arb_exp`, `arb_expm1`, much faster up to a few thousand bits.
- Ported the bit-burst code for high-precision exponentials to the `arb` type.
- Speeded up `arb_log_ui_from_prev`.
- Added `mag_exp`, `mag_expm1`, `mag_exp_tail`, `mag_pow_fmpz`.
- Improved various `mag` functions.
- Added `arb_get/set_interval_mpf`, `arb_get_interval_arf`, and improved `arb_set_interval_arf`.
- Improved `arf_get_fmpz`.
- Prettier printing of complex numbers with negative imaginary part.
- Changed some frequently-used functions from inline to non-inline to reduce code size.

### 11.2.13 2014-08-01 - version 2.2.0

- Added functions for computing polylogarithms and order expansions of polylogarithms, with support for real and complex  $s$ ,  $z$ .
- Added a missing cast affecting C++ compatibility.
- Generalized `powsum` functions to allow a geometric factor.
- Improved `powsum` functions slightly when the exponent is an integer.
- Faster `arb_log_ui_from_prev`.
- Added `mag_sqrt` and `mag_rsqrt` functions.
- Fixed various minor bugs and added missing tests and documentation entries.

### 11.2.14 2014-06-20 - version 2.1.0

- Ported most of the remaining functions to the new arb/acb types, including:
  - Elementary functions (log, atan, etc.).
  - Hypergeometric series summation.
  - The gamma function.
  - The Riemann zeta function and related functions.
  - Bernoulli numbers.
  - The partition function.
  - The calculus modules (rigorous real root isolation, rigorous numerical integration of complex-valued functions).
  - Example programs.
- Added several missing utility functions to the arf and mag modules.

### 11.2.15 2014-05-27 - version 2.0.0

- New modules mag, arf, arb, arb\_poly, arb\_mat, acb, acb\_poly, acb\_mat for higher-performance ball arithmetic.
- Poly\_roots2 and hilbert\_matrix2 example programs.
- Vector dot product and norm functions (contributed by Abhinav Baid).

### 11.2.16 2014-05-03 - version 1.1.0

- Faster and more accurate error bounds for polynomial multiplication (error bounds are now always as good as with classical multiplication, and multiplying high-degree polynomials with approximately equal coefficients now has proper quasilinear complexity).
- Faster and much less memory-hungry exponentials at very high precision.
- Improved the partition function to support n bigger than a single word, and enabled the possibility to use two threads for the computation.
- Fixed a bug in floating-point arithmetic that caused a too small bound for the rounding error to be reported when the result of an inexact operation was rounded up to a power of two (this bug did not affect the correctness of ball arithmetic, because operations on ball midpoints always round down).
- Minor optimizations to floating-point arithmetic.
- Improved argument reduction of the digamma function and short series expansions of the rising factorial.
- Removed the holonomic module for now, as it did not really do anything very useful.

### 11.2.17 2013-12-21 - version 1.0.0

- New example programs directory
  - poly\_roots example program.
  - real\_roots example program.
  - pi\_digits example program.
  - hilbert\_matrix example program.

- keiper\_li example program.
- New fmprb\_calc module for calculus with real functions
  - Bisection-based root isolation.
  - Asymptotically fast Newton root refinement.
- New fmpcb\_calc module for calculus with complex functions
  - Numerical integration using Taylor series.
- Scalar functions
  - Simplified fmprb\_const\_euler using published error bound.
  - Added fmprb\_inv.
  - Added fmprb\_trim, fmpcb\_trim.
  - Added fmpcb\_rsqrt (complex reciprocal square root).
  - Fixed bug in fmprb\_sqrtpos with nonfinite input.
  - Slightly improved fmprb powering code.
  - Added various functions for bounding fmprs by powers of two.
  - Added fmpr\_is\_int.
- Polynomials and power series
  - Implemented scaling to speed up blockwise multiplication.
  - Slightly faster basecase power series exponentials.
  - Improved sin/cos/tan/exp for short power series.
  - Added complex sqrt\_series, rsqrt\_series.
  - Implemented the Riemann-Siegel Z and theta functions for real power series.
  - Added fmprb\_poly\_pow\_series, fmprb\_poly\_pow\_ui and related methods.
  - Added fmprb/fmpcb\_poly\_contains\_fmpz\_poly.
  - Faster composition by monomials.
  - Implemented Borel transform and binomial transform for real power series.
- Matrices
  - Implemented matrix exponentials.
  - Multithreaded fmprb\_mat\_mul.
  - Added matrix infinity norm functions.
  - Added some more matrix-scalar functions.
  - Added matrix contains and overlaps methods.
- Zeta function evaluation
  - Multithreaded power sum evaluation.
  - Faster parameter selection when computing many derivatives.
  - Implemented binary splitting to speed up computing many derivatives.
- Miscellaneous
  - Corrections for C++ compatibility (contributed by Jonathan Bober).
  - Several minor bugfixes and test code enhancements.

### 11.2.18 2013-08-07 - version 0.7

- Floating-point and ball functions
  - Documented, added test code, and fixed bugs for various operations involving a ball containing an infinity or NaN.
  - Added reciprocal square root functions (`fmpr_sqrt`, `fmprb_sqrt`) based on `mpfr_rec_sqrt`.
  - Faster high-precision division by not computing an explicit remainder.
  - Slightly faster computation of pi by using new reciprocal square root and division code.
  - Added an `fmpr` function for approximate division to speed up certain radius operations.
  - Added `fmpr_set_d` for conversion from double.
  - Allow use of doubles to optionally compute the partition function faster but without an error bound.
  - Bypass `mpfr` overflow when computing the exponential function to extremely high precision (approximately 1 billion digits).
  - Made `fmprb_exp` faster for large numbers at extremely high precision by skipping the  $\log(2)$  removal.
  - Made `fmpcb_lgamma` faster at high precision by speeding up the argument reduction branch computation.
  - Added `fmprb_asin`, `fmprb_acos`.
  - Added various other utility functions to the `fmprb` module.
  - Added a function for computing the Glaisher constant.
  - Optimized evaluation of the Riemann zeta function at high precision.
- Polynomials and power series
  - Made squaring of polynomials faster than generic multiplication.
  - Implemented power series reversion (various algorithms) for the `fmprb_poly` type.
  - Added many `fmprb_poly` utility functions (shifting, truncating, setting/getting coefficients, etc.).
  - Improved power series division when either operand is short
  - Improved power series logarithm when the input is short.
  - Improved power series exponential to use the basecase algorithm for short input regardless of the output size.
  - Added power series square root and reciprocal square root.
  - Added `atan`, `tan`, `sin`, `cos`, `sin_cos`, `asin`, `acos` `fmprb_poly` power series functions.
  - Added Newton iteration macros to simplify various functions.
  - Added `gamma` functions of real and complex power series (`[fmprb/fmpcb]_poly_[gamma/rgamma/lgamma]_series`).
  - Added wrappers for computing the Hurwitz zeta function of a power series (`[fmprb/fmpcb]_poly_zeta_series`).
  - Implemented sieving and other optimizations to improve performance for evaluating the zeta function of a short power series.
  - Improved power series composition when the inner series is linear.
  - Added many `fmpcb_poly` versions of nearly all `fmprb_poly` functions.

- Improved speed and stability of series composition/reversion by balancing the power table exponents.
- Other
  - Added support for freeing all cached data by calling `flint_cleanup()`.
  - Introduced `fmprb_ptr`, `fmprb_srcptr`, `fmpcb_ptr`, `fmpcb_srcptr` typedefs for cleaner function signatures.
  - Various bug fixes and general cleanup.

### 11.2.19 2013-05-31 - version 0.6

- Made fast polynomial multiplication over the reals numerically stable by using a blockwise algorithm.
- Disabled default use of the Gauss formula for multiplication of complex polynomials, to improve numerical stability.
- Added division and remainder for complex polynomials.
- Added fast multipoint evaluation and interpolation for complex polynomials.
- Added missing `fmprb_poly_sub` and `fmpcb_poly_sub` functions.
- Faster exponentials (`fmprb_exp` and dependent functions) at low precision, using precomputation.
- Rewrote `fmpr_add` and `fmpr_sub` using `mpn` level code, improving efficiency at low precision.
- Ported the partition function implementation from `flint` (using ball arithmetic in all steps of the calculation to guarantee correctness).
- Ported algorithm for computing the cosine minimal polynomial from `flint` (using ball arithmetic to guarantee correctness).
- Support using GMP instead of MPIR.
- Only use thread-local storage when enabled in `flint`.
- Slightly faster error bounding for the zeta function.
- Added some other helper functions.

### 11.2.20 2013-03-28 - version 0.5

- Arithmetic and elementary functions
  - Added `fmpr_get_fmpz`, `fmpr_get_si`.
  - Fixed accuracy problem with `fmprb_div_2expm1`.
  - Special-cased squaring of complex numbers.
  - Added various `fmpcb` convenience functions (`addmul_ui`, etc).
  - Optimized `fmpr_cmp_2exp_si` and `fmpr_cmpabs_2exp_si`, and added test code for comparison functions.
  - Added `fmprb_atan2`, also fixing a bug in `fmpcb_arg`.
  - Added `fmprb_sin_pi`, `cos_pi`, `sin_cos_pi`, etc.
  - Added `fmprb_sin_pi_fmpq` (etc.) using algebraic methods for fast evaluation of roots of unity.
  - Faster `fmprb_poly_evaluate` and `evaluate_fmpcb` using rectangular splitting.
  - Added `fmprb_poly_evaluate2`, `evaluate2_fmpcb` for simultaneously evaluating the derivative.

- Added `fmprb_poly` root polishing code using near-optimal Newton steps (experimental).
- Added `fmpr_root`, `fmprb_root` (currently based on MPFR).
- Added `fmpr_min`, `fmpr_max`.
- Added `fmprb_set_interval_fmpr`, `fmprb_union`.
- Added `fmpr_bits`, `fmprb_bits`, `fmpcb_bits` for obtaining the mantissa width.
- Added `fmprb_hypot`.
- Added complex square roots.
- Improved `fmprb_log` to slightly improve speed, and properly support huge arguments.
- Fixed `exp`, `cosh`, `sinh` to work with huge arguments.
- Added `fmprb_expm1`.
- Fixed `sin`, `cos`, `atan` to work with huge arguments.
- Improved `fmprb_pow` and `fmpcb_pow`, including automatic detection of small integer and half-integer exponents.
- Added many more elementary functions: `fmprb_tan/cot/tanh/coth`, `fmpcb_tan/cot`, and `pi` versions.
- Added `fmprb_const_e`, `const_log2`, `const_log10`, `const_catalan`.
- Fixed ball containment/overlap checking to work operate efficiently and correctly with huge exponents.
- Strengthened test code for many core operations.
- Special functions
  - Reorganized zeta function related code.
  - Faster evaluation of the Riemann zeta function via sieving.
  - Documented and improved efficiency of the zeta constant binary splitting code.
  - Calculate error bound in Borwein’s algorithm with `fmprs` instead of using doubles.
  - Optimized divisions in zeta evaluation via the Euler product.
  - Use functional equation for Riemann zeta function of a negative argument.
  - Compute single Bernoulli numbers using ball arithmetic instead of relying on the floating-point code in flint.
  - Initial code for evaluating the gamma function using its Taylor series.
  - Much faster rising factorials at high precision, using difference polynomials.
  - Much faster gamma function at high precision.
  - Added complex gamma function, log gamma function, and other versions.
  - Added `fmprb_agm` (real arithmetic-geometric mean).
  - Added `fmprb_gamma_fmpq`, supporting rapid computation of  $\gamma(p/q)$  for  $q = 1, 2, 3, 4, 6$ .
  - Added real and complex digamma function.
  - Fixed unnecessary recomputation of Bernoulli numbers.
  - Optimized computation of Euler’s constant, and added proper error bounds.
  - Avoid reliance on doubles in the hypergeometric series tail bound.
  - Cleaned up factorials and binomials, computing factorials via gamma.
- Other

- Added an `fmpz_extras` module to collect various internal `fmpz` helper functions.
- Fixed detection of flint header files.
- Fixed various other small bugs.

### 11.2.21 2013-01-26 - version 0.4

- Much faster `fmpr_mul`, `fmprr_mul` and `set_round`, resulting in general speed improvements.
- Code for computing the complex Hurwitz zeta function with derivatives.
- Fixed and documented error bounds for hypergeometric series.
- Better algorithm for series evaluation of the gamma function at a rational point.
- Much faster generation of Bernoulli numbers.
- Complex log, exp, pow, trigonometric functions (currently based on MPFR).
- Complex nth roots via Newton iteration.
- Added code for arithmetic on `fmpcb_polys`.
- Code for computing Khinchin's constant.
- Code for rising factorials of polynomials or power series
- Faster `sin_cos`.
- Better `div_2expm1`.
- Many other new helper functions.
- Improved thread safety.
- More test code for core operations.

### 11.2.22 2012-11-07 - version 0.3

- Converted documentation to Sphinx.
- New module `fmpcb` for ball interval arithmetic over the complex numbers
  - Conversions, utility functions and arithmetic operations.
- New module `fmpcb_mat` for matrices over the complex numbers
  - Conversions, utility functions and arithmetic operations.
  - Multiplication, LU decomposition, solving, inverse and determinant.
- New module `fmpcb_poly` for polynomials over the complex numbers
  - Root isolation for complex polynomials.
- New module `fmpz_holonomic` for functions/sequences defined by linear differential/difference equations with polynomial coefficients
  - Functions for creating various special sequences and functions.
  - Some closure properties for sequences.
  - Taylor series expansion for differential equations.
  - Computing the nth entry of a sequence using binary splitting.
  - Computing the nth entry mod p using fast multipoint evaluation.
- Generic binary splitting code with automatic error bounding is now used for evaluating hypergeometric series.

- Matrix powering.
- Various other helper functions.

### **11.2.23 2012-09-29 - version 0.2**

- Code for computing the gamma function (Karatsuba, Stirling's series).
- Rising factorials.
- Fast exp\_series using Newton iteration.
- Improved multiplication of small polynomials by using classical multiplication.
- Implemented error propagation for square roots.
- Polynomial division (Newton-based).
- Polynomial evaluation (Horner) and composition (divide-and-conquer).
- Product trees, fast multipoint evaluation and interpolation (various algorithms).
- Power series composition (Horner, Brent-Kung).
- Added the fmprb\_mat module for matrices of balls of real numbers.
- Matrix multiplication.
- Interval-aware LU decomposition, solving, inverse and determinant.
- Many helper functions and small bugfixes.

### **11.2.24 2012-09-14 - version 0.1**

- 2012-08-05 - Began simplified rewrite.
- 2012-04-05 - Experimental ball and polynomial code (first commit).
